THE TREATMENT OF GONOCOCCIC VAGINITIS WITH THE ESTRO- GENIC HORMONE

FURTHER STUDIES

RICHARD W. TE LINDE, M.D.

BALTIMORE

In 1934 James Brawner and I¹ undertook a study of the treatment of gonococcic vaginitis with estrogenic substance, using amniotin in the various forms that were available at that time. Since our paper published in 1935 we have treated a much larger group of patients, and sufficient time has now elapsed to permit a more seasoned judgment of this treatment. The mode of action of estrogen in curing the disease, the permanence of the cure and the ultimate effect on these young patients have been studied, so that we can now give a more extensive report and arrive at a general evaluation of this method of therapy.

For persons not familiar with the earlier work, a brief review of it is given here. Our work followed that of Lewis,² who conceived the idea that estrogen might be of value in treating gonococcic vaginitis in children. Having used the product hypodermically, he reported the cure of eight patients, in two of whom the vaginitis recurred. The theory on which this method of treatment is founded is based on the well known clinical fact that the young child's vagina is susceptible to gonococcic infections, whereas after puberty the vagina is notably resistant. The histologic difference between the child's vagina, lined with a thin layer of epithelium, and that of the adult, lined with a much thicker layer, is shown in figures 1 and 2. Allen³ showed that this thickening of the epithelial layer could be brought about in the vagina of immature animals by the administration of estrogen. On the basis of this fact, it occurred to Lewis that if this change could be induced in the child's vagina the gonococcic infection might be overcome.

Our earlier work consisted of four experiments in dosage and methods of administration. We first gave amniotin by mouth to six children suffering from vaginitis but were unable to effect any change in the vaginal mucosa. These children were under treatment for from seventy-nine to 123 days, with daily doses of from 3,200 to 16,000 international units. Only one got well, and,

since we could detect no change in her vaginal epithelium, we were not inclined to attribute the cure to the amniotin. (Apparently an occasional child with gonococcic vaginitis gets well spontaneously.) We then treated ten children with daily hypodermic injections of from 400 to 800 international units of amniotin in ethylene glycol solution. The maximum time of treatment of these children was seventy days. None showed any histologic change in the vaginal mucosa. One child got well, but, in view of the absence of changes in the vaginal epithelium, we are not inclined to attribute this cure to the amniotin. It is of interest in this connection to note Witherspoon's⁴ report of complete failure to cure vaginitis with hypodermic injections of amniotin in ten cases. At the time Witherspoon did this work amniotin was marketed only in ethylene glycol solution, and it is noteworthy that we are in complete agreement with him as to the use of amniotin in this solution. Nevertheless, as will be seen from our later studies, his results cannot be taken as a condemnation of the product when used in other vehicles.

Our third experiment consisted of the daily hypodermic administration of the estrogen in oil to twenty-two children with vaginitis. Doses of from 400 to 800 international units were given. Of the twenty-two children, sixteen showed the characteristic vaginal changes in an average of 13.5 days, and the smears became permanently negative in an average time of 17.5 days. It was found that a daily dose of 800 international units was as effective as larger doses. The remaining children failed to respond to the hypodermic administration even when such larger doses were given over a much longer period, but they did respond promptly when treated with suppositories.

Our last experiment consisted of the daily administration to twelve children of vaginal suppositories containing 600 international units of amniotin. All showed the vaginal epithelial response in an average time of 13.1 days, and the smears became permanently negative in 17.8 days. Treatment was continued for several days afterward, so that the average total time of treatment was 26.3 days. It is interesting to note that the average time of treatment necessary for the epithelium to change and the smears to become permanently negative is practically the same for patients cured by suppositories and those cured by the hypodermic administration of amniotin in oil. Figure 3 represents biopsies taken from the vagina before treatment, and figure 4 shows the change to the adult type following the use of suppositories. A typical vaginal smear before treatment is shown in figure 5 and one after treatment in figure 6.

After completing these studies we decided that the treatment of choice was the administration of amniotin by suppository, and up to the present we have cured 175 patients. Although there is some individual difference in the rapidity with which the vagina responds, we have encountered no patient who did not eventually yield to the treatment. In the larger series the average time for epithelial response, as determined by vaginal washings and biopsies, remained at approximately two weeks. Rarely, as long as a month was necessary before the action of the estrogen could be noted, while occasionally a full response was seen in one week. Quite uniformly, the smear becomes negative within a few days after the vagina has begun shedding pure epithelium without pus.

PRESENT ROUTINE OF TREATMENT

The following routine of treatment has been adopted: The mother is told to wash the vulva at the daily bath, but no vaginal irrigations or instillations are used. She is then given a demonstration of how to introduce a suppository into the child's vagina. The suppositories of amniotin for children which are now on the market contain 1,000 international units and have proved most satisfactory. In almost every instance they can be inserted into the child's vagina without difficulty. Only once did we find it necessary to rupture the hymen, with the child under anesthesia, before treatment could be satisfactorily carried out, but it would seem that the better drainage obtained by this procedure in children with minute hymenal orifices is probably also advantageous in clearing up the infection. Although the 1,000 international unit suppositories are of higher dosage than the suppositories containing 600 international units, used in our earlier work, we have seen no advantage or disadvantage in the increased dose. One suppository is introduced daily at bedtime.

The patients are brought back to the clinic at weekly intervals, when vaginal smears and washings are made. The washings are made with a small medicine dropper

Fig. 1.—The normal vagina of a child aged 14 months (autopsy).

and examined under low magnification. As soon as the vagina is well under the influence of the estrogen, epithelial desquamation begins. At times this is so profuse as to cause the mother to fear that there is an increased amount of pus. But as soon as this epithelial response takes place, the vulval reddening begins to clear up, and in a few days the smear usually becomes negative. We insist on the smears being stained by the Gram method, so that the gonococci can be differentiated from gram-positive cocci of like structure. When the gonococci are numerous and many typical cells loaded with diplococci are observed, little difficulty is experienced in interpreting the smear, but as the condition begins to clear up and the organisms become scarce the great advantage in the differential stain becomes apparent.

After the first negative smear the treatment is continued for two more weeks, and if the weekly smears continue to be negative it is discontinued. In the average case, the entire treatment extends over about a month. It is possible that in some cases treatment could be discontinued in less than two weeks after the smears become permanently negative, but since we have been following this routine recurrences have been rare, whereas when we discontinued treatment sooner, in our earlier studies, they were more frequent. The children are brought back to the clinic one and two months after discontinuing treatment, as a matter of dispensary routine, but for research purposes our first hundred patients were followed much longer.

Fig. 2.—The normal adult vagina; specimen taken from a woman aged 37.

At the time of our first paper a question was raised by many persons, including ourselves, as to the permanence of the cures. Owing to the short time which had elapsed, we were unable to answer this question. Since then we have made a follow-up study of the first 100 cured patients. Of these children ninety-eight were well at the time of the last examination, from three months to two and one-half years after the cessation of treatment. Whether the two children who were found to have vaginitis at the time of the check-up represent recurrences or reinfection is debatable. Considering the prevalence of gonococcic infections in the Negro homes from which most of these children come, there is the distinct possibility of reinfection. At any rate the percentage of permanent cures may be said to be 98 in this group.

The possibility of harm to young patients with vaginitis through the administration of estrogen has been uppermost in our minds since we began this study. In our first publication we reported no harm to the patients except for some localized painful induration at the site of the injection when the amniotin was given in oil. This effect we considered a distinct disadvantage of this form of treatment but it has been overcome by the substitution of vaginal suppositories. No cases of salpingitis were noted in our first series of thirty-five cases, and none have been noted in our present series of 175 cases.

In the light of further experience the ultimate effect of the estrogen on the genital tract may now be considered. From the laboratory standpoint the work of several investigators has a bearing on the question. Allen and Diddle⁵ gave monkeys amniotin (hypodermically) in doses comparable to those received by our children. Examination of the monkeys' ovaries thirty days after the cessation of treatment showed them to be normal histologically.

The results of Shumacker's⁶ work on mice coincided with those of Diddle and Allen. Leonard, Meyer and

5. Allen, Edgar, and Diddle, A. W.: Ovarian Follicular Hormone Effects on the Ovaries, *Am. J. Obst. & Gynec.* 29: 83 (Jan.) 1935.
6. Shumacker, H. B.: Personal communication to the author.

Hisaw⁷ working on immature rats, found that the administration of the follicular hormone begun early in life and continued beyond the time of normal sexual maturity prevented the full development of the ovaries. The ovaries of the treated animals contained fewer follicles and corpora lutea and weighed from 43 to 49 per cent less than those of the untreated animals. They concluded that this was not a direct effect on the ovaries but was the result of the action of the estrogenic substance on the anterior lobe of the pituitary. They based this belief on the experimentally demonstrable fact that the implanted pituitaries of the treated rats were less potent than the pituitaries of untreated rats in their ability to produce sexual precocity in the immature female.

Hisaw and his collaborators found, however, that when the injection of estrogen was discontinued before the animals were sexually mature no outstanding changes could be noted in the ovaries. When one considers the short span of their immature life during which children with gonococcic vaginitis received the estrogen, there is nothing in Hisaw's data which would indicate that the clinical use of this substance in the treatment of vaginitis is harmful. Mazer and Israel⁸ found that the injection of 160 international units twice weekly for four months produced no ill effect in infantile rats.

In our early cases of hypodermic administration we observed definite hypertrophy of the breasts in most of the children who received any great quantity of amniotin. On the other hand, the children who received amniotin vaginally showed no changes in the breasts. This difference suggested that when the substance was administered by the vagina there was little general absorption and that the more marked effect noted in the vaginal mucosa might be due to greater local concentration. Our subsequent larger series in general confirms this idea, but in two patients treated vaginally we noted slight changes in the breasts, indicating in rare instances some general absorption. We attempted to study the absorption and the excretion of amniotin administered by the vagina by making quantitative determinations of the estrogen in the twenty-four hour output of urine. By estimating the amount of estrogen in the blood and the amount in the urine simultaneously, Mazer and Israel⁸ have shown that the content in the urine reflects fairly accurately the amount in the blood. We first determined the estrogen output of twenty-five normal children. Practically every child excreted less than 2 rat units to a twenty-four hour specimen. Determinations were then made on the twenty-four hour specimens of children whose vaginal washings and biopsy specimens showed them to be under the influence of the amniotin. The determinations were made on the day following the administration of the last suppository. The results of these determinations showed, in practically every case, less than 2 rat units to a twenty-four hour specimen.

If one assumes the parallelism between the amount of estrogen excreted and the amount in the circulating blood, as shown by Mazer and Israel, these results suggest little general absorption of amniotin when it is given by the vagina. The possibility that the excretion in immature children may not be a true index of the

absorption, as in adults, because of the storage of estrogen, must be considered. We believe that the prolonged storage in children is unlikely because the effect on the vaginal mucosa does not persist long. As evidence of this is the fact that vaginal biopsies regularly show a return to the immature type in from four to six weeks.

The last word concerning the possible harmful effect of estrogenic substance cannot be said until a group of children treated with it have reached maturity and borne children. At this time, however, it is possible to say that all of the children so treated seem to be developing normally as far as can be determined by examination of the external and the internal genitalia. Of the 175 children whom we have treated, two have reached or passed the age of 13. One of these began to menstruate ten months ago and has menstruated regularly since. The other, at 14, has just had her first period. Another child had her first period three months ago, at 11 years, and has menstruated regularly since. In view of this clinical and laboratory experience we believe that up to date no evidence has been found that the treatment is harmful.

The *modus operandi* by which the gonococcus is eliminated from the child's vagina has been the subject of some speculation. Lewis and Weinstein⁹ have suggested that the increased acidity noted as a result of the estrogenic action is the essential factor in eliminating the infection. *In vitro* the gonococcus grows best in a medium with a p_H of from 7.2 to 7.6. The organism is very sensitive to higher acidity and rarely grows in a medium as acid as p_H 6 or 6.2. Lewis and Weinstein showed that

Fig. 3.—Biopsy specimen from the vagina of a child before treatment. Note the marked infiltration of inflammatory cells and the complete absence of epithelium.

after the vaginal mucosa has reacted to estrogen there is a well marked acidity, the p_H ranging from 4.8 to 6. Our results confirmed this observation. In a series of twenty cases of untreated gonococcic vaginitis the average vaginal p_H was 7.5. After adequate treatment with amniotin suppositories the average p_H was 5. Lewis and Weinstein concluded that this greater acidity is responsible for the disappearance of the gonococcus.

In order to cast some light on this question, we first made careful observations on the vaginal acidity of twenty-five normal children aged from 3 to 14 years, using nitrazine paper wrapped about a toothpick swab inserted into the vagina. We found that those aged from 3 to 10 years (seventeen children) had an average vaginal p_H of 7.3, whereas the average p_H for children from 11 to 14 years old (eight children) was 4.5. The fact that gonococcic vaginitis tends to disappear spontaneously at the approach of puberty, when this decided increase in acidity occurs, seems to favor Lewis's view. However, one must not lose sight of the

fact that at puberty there is also a histologic change in the epithelial covering of the vagina, which may also be an important factor in the clearing up of the vaginitis.

It occurred to us that if the increased acidity was the sole factor in clearing up the infection we might accomplish the same end by increasing the acidity by another method. Karnaky¹⁰ had already reported success in clearing up vaginitis by acidifying the vagina. For this purpose he used a vaginal suppository of a preparation called floraquin. Each suppository contained 1½ grains (0.1 Gm.) of diodoquin, lactose, dextrose and boric acid. We treated a series of seventeen children by the insertion twice or three times daily of a suppository into the vagina. We were able to increase the average acidity from p_H 7.5 before the treatment to p_H 5.7. This is well below the point at which the gonococcus will grow *in vitro*. With the increased acidity Döderlein's bacilli appeared in the

vagina to some degree in each case. The patients were treated for from thirty-five to 123 days. Seven became free from infection and were clinically well. They have remained well from one to seven months, as determined at our last check-up. Five got well and relapsed from eleven days to three months after cessation of treatment. Of course we required three negative smears at weekly intervals before stopping treatment in these cases as well as in those in which amniotin was given. In five cases the condition failed to clear up even though the treatment was continued for many times as long a period as is necessary to cure the vaginitis with amniotin.

In one case the vaginal acidifying was continued for 123 days with no effect on the infection. Even in those cases in which the gonococcus failed to be eradicated, Döderlein's bacilli appeared, occurring in the smears along with the gonococci. It may be said, however, that in those cases in which Döderlein's bacilli appeared in great numbers the acidity was usually greatest and the gonococcus absent.

We concluded from these experiments that, although the vagina could be made acid with floraquin (p_H 5.7) to a degree beyond the acidity at which the gonococcus will grow *in vitro*, the results in clearing up the infection were much less satisfactory than with amniotin. Vaginal specimens for biopsy taken after treatment with floraquin usually showed a covering of the ulcerated surface but not the marked epithelial thickening noted after treatment with amniotin, and, although the vaginal surface was often healed, a marked subepithelial infiltration with inflammatory

cells frequently remained. It would seem, then, that the increased acidity brought about either by direct acidifying or by the use of amniotin is detrimental to the growth of gonococci in the vagina. Still the fact that the results are so much better when amniotin is used would indicate that another factor exists which is not present when the vagina is acidified directly.

At the present time we are unable to prove definitely what this other factor is, but we are inclined to believe that the simple healing of the ulceration and the complete covering of the vagina with a thick adult type of epithelium has an important part in the eradication of the infection. Biopsy specimens taken before treatment usually showed marked ulceration, whereas after treatment a thick intact epithelial surface was present. We believe, after studying biopsy specimens from the vaginal wall taken at various times in the course of the treatment, that the gonococcus does not live long when buried in the tissues. It is possible to watch the gradual subsidence of the inflammatory process in the subepithelial tissues after the surface has become epithelized. Curtis has shown in his bacteriologic studies that the gonococcus does not live long buried in the walls of the tubes. Seldom could he obtain the gonococcus in culture more than two weeks after the subsidence of the fever and the leukocytosis. Our histologic studies on the vaginal wall tend to show the same subsidence of the inflammation after surface epithelization, whereas in the case of untreated vaginitis the deeper tissues are constantly subject to reinfection from the surface growth. After estrogen has produced an adult type of epithelium there is a barrier which the gonococcus apparently cannot invade. With the increased acidity of the vaginal secretions and the resultant death of the surface organisms there remains the destruction of the organisms deep in the tissues before a permanent cure can be effected. Judging from our histologic studies, this always occurs when the vaginal surface becomes covered with the adult type of epithelium.

Before we conclude this report on gonococcal vaginitis it would seem in order to discuss briefly a few points regarding the nature of the disease which have become apparent in our observation of this large series of cases. Much has been written concerning the involvement of the cervix, urethra and rectum. The literature contains many statements regarding cervical involvement which are at extreme variance. Perrin¹¹ in 1911 stated that the essential lesion is "endometritis of the neck of the cervix." Rubin and Leopold¹² believed the cervix is involved because the infection persists after prolonged treatment. Burnet¹³ went so far as to say that, whereas inflammation of the vagina is present in many cases, it is mild and subsides rapidly as the infection in the cervix gains a foothold. Stein¹⁴ suggested the term "vulvocervicitis" as being more descriptive of the actual lesion.

In answer to those workers who consider the vaginitis slight or nonexistent, one has only to refer them to our figure 3. We have made more than a hundred vaginal biopsies for patients with acute and chronic forms of the disease, all of which showed inflammation of the vagina, often with marked ulceration. Reichert

Fig. 4.—Biopsy specimen from a child's vagina taken on the twenty-fifth day of treatment. Note the marked thickening of the epithelium and the total absence of inflammatory products.

and his co-workers¹⁵ reported a 98 per cent involvement of the cervix. We have no objection to this figure if it refers to the vaginal portion of the cervix, but our observations have pointed strongly against involvement of the endocervix. Inspection of the vaginal portion of the cervix through a Kelly speculum often shows it to be as red and granular as the inflamed vagina. After treatment it becomes pale pink, like the vagina. This direct observation leaves little doubt that the vaginal portion of the cervix is involved with the vagina. But after all, histologically the vaginal portion of the cervix is merely a continuation of the vagina; the endocervix, lined with columnar epithelium, is an entirely different structure.

After adequate treatment of the vagina with amniotin we have seen no evidence of a persistence of the infection in the endocervix. We have no doubt that gonococci can be recovered from the cervical canal during the active stage of the vaginitis, when the cervix is bathed in pus, but we have seen no evidence of an endocervicitis comparable to that of the adult. If the tissues of the endocervix were involved, one would expect the infection to persist there in some cases after the clearing up of the infection in the vagina as a result of the action of the hormone on the vaginal mucosa. Our results show that it does not do so.

As in the case of the cervix, there is a wide divergence of opinion as to urethral involvement. Some investigators state that urethral involvement has no part in determining the course of the disease. At the other extreme is Stein, who stated that urethritis is an "inevitable complication." Other workers estimate the

It is true that at times the meatus, along with the other tissues of the vaginal vestibule, is red and edematous. It is also true that positive smears can often be obtained from the urethra, but this is no more than can be expected when the meatus is bathed in pus and there is no tight sphincter at the external meatus. The fact that the organisms frequently enter the urethra without

Fig. 6.—A stained vaginal smear taken after fifteen days of treatment.

giving rise to symptoms of clinical urethritis indicates resistance rather than susceptibility on the part of the young urethra to gonococcal infection. In our series, after the clearing up of the vaginitis with amniotin there was in no case any evidence of a residual infection in the urethra.

In regard to gonococcal proctitis in children, the views expressed in the literature vary greatly. At one extreme is the work of Ruys and Jens,¹⁶ who found gonococci in the rectum in 100 per cent of their series. At the other extreme are Reichert and his co-workers,¹⁵ who, in spite of routine cultures and smears of material from the rectum, together with proctoscopic examinations, found no instance of rectal or anal disease. Our views are in complete accord with those of Reichert. Although we did not regularly make smears or cultures of material from the rectum we did make routine digital rectal examinations, and in no case could we find any evidence of proctitis. We are inclined to feel that many observers who have obtained positive smears from the rectum have, on that basis, assumed the existence of proctitis, but certainly the presence of gonococci in the rectum does not necessarily mean proctitis. Is it not more probable that the presence of gonococci in the rectum without evidence of proctitis would indicate a resistance of the tissue to invasion by that organism?

SUMMARY

We have reported the cure of 175 patients with gonococcal vaginitis by amniotin. All, except sixteen of those to whom the product was given hypodermically in oil, were cured by the use of amniotin vaginal suppositories. We have yet to encounter a patient who failed to get well by this method of treatment, and we consider it a very satisfactory way of dealing with the

Fig. 5.—A stained vaginal smear taken before treatment.

rate of urethral involvement as from 10 to 20 per cent. Unrecognized urethral involvement has been blamed as a common cause of relapse. According to our experience urethritis is certainly in the vast majority of cases not a part of the pathologic process. We base this opinion on the fact that the classic symptom of urethritis, burning on urination, was not complained of by any of our children, although many of them were old enough to give an intelligent history.

disease. A follow-up of our first 100 patients, from three months to two and one-half years after the last treatment, showed ninety-eight of them well. We saw no clinical evidence of harm due to the treatment, and laboratory investigations confirm this observation. We feel that the increased acidity brought about in the vagina by the action of the estrogen is a factor in overcoming the infection, but, since our results were not nearly so good when another acidifying suppository was employed, we believe that amniotin introduces an additional factor. We are inclined to think that this other factor is the covering of the vagina with thick epithelium, which prevents reinfection of the subepithelial tissues and thus permits the inflammatory process in them to subside. Our clinical observations and biopsies have indicated that the essential lesion of gonococcal infection of the lower part of the genital tract in female children is vaginitis.

STUDIES IN NODULAR GOITER

I. INCIDENCE OF THYROID NODULES IN ROUTINE NECROPSIES IN A NONGOITROUS REGION

M. J. SCHLESINGER, M.D.

S. L. GARGILL, M.D.

AND

I. H. SAXE, M.D.

BOSTON

The relative frequency of nodular and of nonnodular thyroid glands in both goitrous and nongoitrous districts has been repeatedly studied in Europe.¹ The few such studies in this country² deal exclusively with material from goitrous districts. Apparently no such survey in an Americal nongoitrous district has ever been made.

Aschoff³ and Clerc⁴ state that in nongoitrous regions nodules in the thyroid gland are just as common as in goitrous regions but that they are usually microscopic. However, in our routine autopsy material, from a nongoitrous district, we encountered what seemed an unusually large number of thyroid nodules of fair size. Most of these nodules discovered post mortem had not been palpated ante mortem. This was disturbing in view of the current tendency to regard all such nodules as potentially malignant and to advise their

extirpation as prophylactic treatment against the development of carcinoma of the thyroid gland.⁵

Because of the apparent lack of a similar study in nongoitrous regions elsewhere in this country, and because of our impression that nodules in the thyroid gland are more common than clinically suspected in such districts, we have reviewed the autopsy material available in Boston.

NATURE AND SELECTION OF MATERIAL

The material studied consisted of 2,185 recent complete autopsy protocols from three large teaching hospitals in Boston. In only 1,371 of these autopsies had the thyroid gland been examined, because of limitations of incisions or other restrictions. Since the recorded descriptions of such examinations were often meager, the adoption of some strict and absolute criterion of a nodule became necessary. Since we were primarily interested in the clinical significance of such nodules, it was felt that the adopted standard should be applicable to the clinical examination of the patient. From an academic point of view, or even from the point of view of their potential danger, small nodules are possibly as important as larger ones. However, if a nodule is too small to be readily palpable, it is of no "clinical" significance. Therefore, in order that the studies might be directly transferred to the clinic, only nodules of 1 cm. or more in average diameter were included in our figures. Nodules of this size should be easily palpable clinically, at least if they are in an exposed position.

Other reports² make no exact statement concerning the size of the nodules considered, and presumably they included smaller nodules than we have selected. Thus our incidence of nodular thyroid glands will be lower than if all "nodules" encountered had been included. Also, if the autopsy protocol stated no actual dimensions of a nodule described, the thyroid gland was tabulated as in the nonnodular group. Our final figures, therefore, because we limited them to nodules measuring 1 cm. or more, not only do not include all nodules but also err on the side of omitting some observed nodules that should be clinically palpable. Moreover, since in the clinical appreciation of a nodule not only its size but its consistency is an important factor, the selection of nodules was further restricted to distinct, separate, individual masses, clearly demarcated and grossly different in texture, consistency and appearance from the surrounding thyroid tissue.

RESULTS AND COMMENT

In table 1 are given the complete data, arranged according to the hospital from which they were obtained and giving the general average incidence of nodules, as well as their distribution among males and females of all ages, and in those over the age of 50. It will be noted that the incidence of nodules averages 8.2 per cent of all the specimens examined. This figure is markedly lower than that found in goitrous districts. However, the striking point is the difference in incidence between the three hospitals in the same city, varying between 5.2 and 14.9 per cent. The slight difference in the sources from which these three hospitals in Boston draw their patients does not seem sufficient to explain this discrepancy. Thus the patients of hospital 2 are almost

entirely residents of Boston. Hospital 1 has a population largely from Boston and its close vicinity, with a moderate number of patients from not only all of New England but from all parts of the country. Hospital 3, with the largest percentage of nodular thyroid glands, has a clientele largely Jewish, whereas in the other two hospitals the opposite is true.

Fig. 1.—Section of colloid nodule slightly reduced from a photomicrograph with a magnification of 14 diameters.

As regards the distribution of nodules between men and women of the whole group and also in that portion of the group over 50 years of age, our observations are in accord with those in previously reported series of this nature, in that we found a higher incidence of

in the selected groups over 50 years of age. Over this age the proportion of women to men is slightly larger than in the younger group.

Special attention is called to the incidence of 37.2 per cent of nodules in women over 50 years of age in hospital 3. This incidence approaches that found in goitrous districts. It is not nearly approached in the other two hospitals. Hospital 3 has about 80 per cent of Jewish patients, which it draws largely from Boston and its immediate vicinity. These patients have come from all parts of the world but have spent the major part of their life, although not their adolescence, in or

near Boston. Hospital 2 caters to a similar group of patients, but a much smaller proportion of them are Jewish. It has an intermediate incidence of nodules between hospital 3 and hospital 1. There is, in general, a more widespread origin of patients in hospital 1 than in either of the other two hospitals.

nodules in the thyroid glands of women than of men, and also that such nodules are more frequently found with increasing age. However, the ratios of women to men with nodular thyroid glands in reports from goitrous districts vary from 10:1 to 4:1.⁶ In our series, this ratio is only about 2:1. Thus the influences at work, whatever they may be, resulting in nodules in the thyroid gland in nongoitrous districts, affect men and women more nearly alike. The proportionately larger number of nodules in women is seen in all the individual figures from the several hospitals and also

Fig. 2.—Section of fetal adenomatous nodule slightly reduced from a photomicrograph with a magnification of 100 diameters.

The increasing incidence of nodules in the thyroid gland with age and the marked increase over the age of 50, especially in women, are more sharply emphasized in table 2. Here the figures are arranged according to age in decades and according to sex. It will be noted that no nodules were found in the 144 glands from men under 40, whereas seven nodular thyroid glands were

6. Wegelin.¹ Hertzler.²

found in the 115 women in this age group. Thus, women not only show a higher incidence of thyroid gland nodules in a nongoitrous district but such nodules appear at a much earlier age than in men. In goitrous districts nodular thyroid glands are not uncommon even in young girls.⁷

Fig. 3.—Section of embryonal adenomatous nodule slightly reduced from a photomicrograph with a magnification of 250 diameters.

Not wishing at this time to enter into the much disputed question as to the origin and nature of these nodules in the thyroid gland, or whether or not some or all of them are true neoplastic adenomas, we have indiscriminately classified all masses having the char-

acteristics already noted as nodules. In only seventy-four of the selected nodular thyroid glands were microscopic sections available. We have reviewed these slides and classified them according to the divisions we at present recognize. The classification is based on the predominating type of structure present, with full recognition that many of these nodules present a mixed tissue structure. Our grouping consists of four divisions: (1) colloid nodules, subdivided into those without and those with degenerative, but nonmalignant, changes; (2) fetal adenomas; (3) embryonal adenomas; (4) malignant neoplasms. The accompanying

photomicrographs illustrate these four types. In the present series no embryonal adenomas were encountered.

In table 3 is shown the type distribution according to age and sex of the seventy-four nodules examined microscopically. There is no striking difference in the nature of the nodules in the two sexes, which again emphasizes that in nongoitrous districts the sex of the patient is of less moment in the development of a nodule in the thyroid gland. The true malignant neoplasms, of which one was a sarcoma and five were carcinomas, occurred between the ages of 30 and 70, the usual cancer age. The few fetal adenomas encoun-

tered tend to be found in a slightly older age group, and the majority of the colloid nodules, both simple and those presenting degenerative changes, in distinctly older age periods.

In our series from one nongoitrous district a large proportion of the colloid nodules show degenerative changes. The nearest comparable group from a goitrous district is found in Rice's² report on sixty-seven thyroid glands with single nodules seen post

Fig. 4.—Section of carcinoma slightly reduced from a photomicrograph with a magnification of 65 diameters.

mortem. The percentage distribution of the types of nodules in these two series is compared in table 4. There is a strikingly greater degree of degenerative change in the colloid nodules in our series as compared to that found by Rice in a goitrous district, although the total percentage of such nodules is about the same. This is further evidence that in a nongoitrous district the etiologic factors for the formation and persistence

of nodules are more transitory as well as less common. The percentage incidence of so-called fetal adenomas is practically the same in the two series.

Malignant neoplasms are conspicuous by their absence in Rice's series despite the fact that it consists of single nodules in postmortem specimens of thyroid glands from a goitrous region. The total of six malignant tumors encountered in our series, as indicated, comprises 8.1 per cent of the seventy-four nodules the nature of which was determined microscopically. However, of these six tumors one was a sarcoma and the other five were definite carcinomas. These six tumors probably represent all the malignant neoplasms of the thyroid gland in the total of 1,371 thyroid glands examined post mortem, thus giving a crude incidence of 0.4 per cent of thyroid gland malignancy in the whole series. Also, the five carcinomas represent only 4.5 per cent of the 112 nodular thyroid glands encountered. This incidence coincides fairly well with that reported from other clinics. Thus, Speese and Brown⁸ give the incidence of malignancy as 4.6 per cent of nodular goiters, Walton⁹ as 3.2 per cent, and Pemberton¹⁰ as 2.7 per cent. Means,¹¹ in the most recent report from the Massachusetts General Hospital, gives the incidence of cancer of the thyroid as 3.2 per cent of nodular goiters.

SUMMARY

The relative frequency of nodular and nonnodular thyroid glands in a nongoitrous region has been studied by reviewing 2,185 recent complete autopsy protocols in three large teaching hospitals in Boston. In such a district, 8.2 per cent of thyroid glands adequately examined post mortem contained nodules which should have been clinically palpable, namely 1 cm. or more in diameter.

The incidence of such nodules was found to be higher in women than in men by approximately 2 to 1 in such a district.

Such nodules were rarely encountered under 30 years of age in either men or women. In women over 50 the average incidence of such nodules was 15.2 per cent, and close to 40 per cent in selected groups.

Most of these nodules were of the colloid type, and the majority of them showed nonmalignant degenerative changes.

Six malignant neoplasms (0.4 per cent) were found in the 1,373 adequately examined thyroid glands. In the 112 nodular thyroid glands, 4.5 per cent were carcinomatous nodules.

CONCLUSIONS

1. Under the age of 30 in a man or woman in a nongoitrous district a palpable nodule in the thyroid should be considered potentially malignant and be surgically extirpated.

2. Between the ages of 30 and 50 years, because of the general higher susceptibility to carcinoma, this potentiality becomes greater. A larger portion of such nodules, surgically examined at this later age, however, will prove to be benign.

3. After the age of 50, nodules in the thyroid are so common as to be almost physiologic, especially in women.

RHINOSPORIDIOSIS IN THE UNITED STATES

REPORT OF A CASE ORIGINATING IN TEXAS

GEORGE T. CALDWELL, M.D.

DALLAS, TEXAS

AND

J. D. ROBERTS, M.D.

LONGVIEW, TEXAS

Approximately one year ago, Dr. J. D. Roberts submitted for microscopic study an unusual polypoid mass removed by him from the nose of a patient residing in eastern Texas. The sections prepared from this mass revealed large endosporulating organisms in various stages of their development and obviously different from any organisms previously encountered in the study of surgical or of autopsy material. No great

Fig. 1.—Immature and mature forms of *Rhinosporidium seeberi* in polyp from nasal septum, including one ruptured sporangium with numerous recently discharged endospores in adjacent lesion.

difficulty, however, was experienced in finding adequate descriptions of these organisms and of the lesions which they produce. About the same time a paper on the pathology of rhinosporidiosis by Karunaratne¹ of the Ceylon Medical College appeared, covering the main features of the disease and its causative agent.

Rhinosporidiosis, as the name implies, involves most frequently nasal structures, especially the nasal septum. It is a comparatively rare disease of world-wide distribution, produced by a readily demonstrable endosporulating vegetable parasite known as *Rhinosporidium seeberi*. The disease has been recognized most frequently in India and on the neighboring island of

1. Karunaratne, W. A. E.: The Pathology of Rhinosporidiosis, *J. Path. & Bact.* 42: 193-202 (Jan.) 1936.

Ceylon. The first case of rhinosporidiosis, however, was reported by Guillermo Seeber² of Buenos Aires in 1900.

Thus far only six previous cases have been recognized and reported in the United States or, for that matter, in

moved with his father and mother to Kilgore, Texas, in 1931. The father and mother are living and well. No member of the family has done any traveling except in Texas and Oklahoma.

The patient complained of nosebleed from the right side of nose for three or four months. He had noticed a small mass in the right side of the nose for two months. Examination revealed a coarsely lobulated polypoid mass attached to the anterior superior part of the right side of the nasal septum.

The tumor, a reddish gray mass measuring 1.3 by 0.7 by 0.4 cm., was removed by Dr. J. D. Roberts, April 14, 1936.

Microscopic Changes.—Microscopic examination revealed that the polypoid mass was formed chiefly of an edematous, vascular fibrous tissue throughout which there were scattered many perfectly round, encapsulated cystlike structures varying in

which some of the sporangia had recently ruptured, discharging the released endospores over the outer surface of the tumor mass. In some of these superficial areas the organisms were so numerous that as many as fifty could be seen within the limits of a single low power field.

Many of the young or immature organisms possess a single ovum-like cell centrally placed, surrounded by a finely granular

Fig. 4.—Large immature sporangia showing the formation of the endospores.

cytoplasmic mass. In slightly more mature forms, a network of orderly strands radiated out in all directions to the capsule. Definite chromatin particles appeared along these threadlike strands at a later stage, giving a reticulated appearance to the encapsulated substance. Many more mature organisms were present, in which the cytoplasmic contents were now definitely segmented to form the numerous endospores. These mature sporangia could be seen to contain many hundreds or even several thousands of the spherical endospores.

When the endospores were liberated from the sporangia within the supporting tissues of the polyp, the injury produced led to a localized area of necrosis, accompanied by an intense inflammatory reaction in which polymorphonuclear leukocytes predominated with scattered lymphoid cells and plasma cells. The capsules of the ruptured sporangia were conspicuous in these lesions; some appeared to have turned completely inside out as a result of the elastic properties of the ruptured capsules. A few of the older local lesions were proliferative in type with the formation of epithelioid cells and an occasional giant cell. These inflammatory processes with the resulting fibrosis largely accounted for the gradual increase in the size of the polypoid mass.

COMMENT

Location of Lesions.—In the seven North American cases, the lesions have been in the nose in every instance, and apparently at first on the nasal septum. They have been located most frequently on the right side of the nasal septum, near the junction of the cartilaginous and bony portions of the septum and situated well above the floor of the nares. In the eighty-eight cases reviewed

by Karunaratne, seventy-one were nasal, ten were conjunctival, three involved the lacrimal sac, one the uvula, one the external auditory meatus and one the penis.

Lesions Produced.—The more frequent nasal lesion is usually a pedunculated growth attached by a definite stalk to the mucous membrane, most often of the vestibular region. Multiple masses are not particularly uncommon. Some of these appear to be implantations on adjacent mucous surfaces. Recurrences are not infrequent following surgical removal.

According to Karunaratne, these polypoid masses are usually pink or red and the surfaces are often roughened by papillary projections. Mature sporangia projecting beneath the surface epithelium may be seen with the naked eye as minute white or translucent dots. Some of these sporangia rupture through the surface epithelium and discharge their numerous spores directly over the surface of the tumor mass, where they are incorporated in the mucous secretions. Smears of this mucus may be found to contain both the spores and the unruptured sporangia.

Ashworth³ in 1923 published a detailed account of the developmental cycle of the organism that is responsible for these lesions, wherever they occur throughout the world. He established the vegetable nature of the parasite and classified it among the Phycomycetes, giving the organism its present name, *Rhinosporidium*

Fig. 5.—Sporangia discharging mature spores through surface epithelium.

seeberi. According to Ashworth's description the earliest stage of the parasite is a round or oval cell about the size of a red blood cell. This cell has a peculiarly vacuolated chitinous membrane. As the organism grows, granules appear in the cytoplasm and when it

3. Ashworth, J. H.: On *Rhinosporidium Seeberi*, with Special Reference to Its Sporulation and Affinities, *Tr. Roy. Soc. Edinburgh* 53 (part 2): 301-342, 1923.

reaches a diameter of 50 or 60 microns mitotic division begins in the nucleus. Repeated mitotic divisions occur until about the 2,000 nucleus stage before the cytoplasm shows any evidence of division. With the maturation of the spores the sporangium enlarges until it reaches a diameter of about 200 to 300 microns. Only a variable proportion of the spores reach maturity, while the rest remain undeveloped. The matured spores occupy the periphery of the sporangium while the immature ones are at the center. When the thin film over the pore ruptures, some mucoid material is said to escape along with the spores.

Fig. 6.—Higher magnification of mature spores in mucus on the surface of the polypoid mass.

Mode of Infection.—Nothing definite is known about the modes of infection and transmission, except that the presence of infection in nearby sites is strongly suggestive of autoinoculation. Attempts have been made to account for the marked preponderance of the disease in males on an occupational basis but no very definite lead has been established, although several instances of the disease have been observed in farm animals, such as the horse, mule and bullock.

The organism has not been grown with certainty on artificial mediums and it has not been possible to transmit the disease to experimental animals, although rabbits, guinea pigs, mice and monkeys have been inoculated with materials containing the organisms.

SUMMARY

The case of rhinosporidiosis here reported is apparently the first of its kind known to have occurred in the Southwest. The causative agent, which is so conspicuous in the lesion, possesses all the morphologic features of *Rhinosporidium seeberi* as described by Ashworth and as found in previously reported cases throughout the world.

VASCULAR BIRTHMARKS

TREATMENT WITH INJECTION OF SCLEROSING SOLUTION

HENRY W. KAESSLER, M.D.

BRONXVILLE-MOUNT VERNON, N. Y.

Chiefly because of their cosmetic importance but also because of their hemorrhagic annoyance and occasional invasive and metastasizing propensity, vascular nevi should be eradicated early. There are two types commonly encountered in pediatric practice and readily amenable to treatment, the hemangioma cavernosum or strawberry birthmark, and the hemangioma hypertrophicum or hemangio-endothelioma.

The hemangioma cavernosum is a mass of convoluted arterioles and venules with many cystic dilatations and sacculations lined by a single layer of capillary endothelium filled with serum or blood. There is little connective tissue. The lesions may be flat or elevated above the adjacent skin or mucous membrane area. They may involve either the skin or subcutaneous tissue or both. Both skin and mucous membrane may be involved at the mucocutaneous junctions. When superficial, they are a brilliant scarlet; if deeply subcutaneous, blue. The surface is usually soft and papillomatous. The mass is spongy and, when firmly compressed, blanches.

The hemangioma hypertrophicum is a more cellular form of vascular nevus. In this lesion a prolific growth of vascular endothelial cells narrows or completely obliterates the lumen of the blood vessels. There are interspersed in the masses of cells cystic dilatations, as in the cavernous type of hemangioma, but relatively few in number. Being less vascular in structure the mass is pale blue or gray, not as spongy, and less compressible than the cavernous type. Lesions may be characteristic of both types.

Fig. 1.—Typical facial hemangioma: A, at age of 8 months. Therapy begun at 10 months. Lesions subjected to five injection treatments during subsequent three months. B, appearance of site of lesion at age of 4½ years, three years after treatment.

Generally these lesions are first observed at birth or shortly thereafter as tiny, apparently insignificant, red or bluish spots, attaining appreciable size after a few weeks. Cessation of growth and spontaneous involution may occur but there are no characteristic indications of this ultimate prognosis.

From Pediatric Service, Grasslands Hospital, Valhalla, N. Y.
Dr. F. D. Barnes, director.

Study of the origin and growth of these lesions by Ribbert, by injection methods, indicated that the vessels have few or no lateral anastomoses and that the growth of the tumor is by displacement and compression of the invaded parts. There is no direct extension to the healthy vessels of the neighboring areas. Injected material passes freely through the efferent and afferent vessels and does not enter the vessels of adjacent tissue. Explanations of the etiology appear to resolve into a vague "congenital tissue predisposition" as suggested by Ewing. Apparently the tumor process is largely one of hyperplasia of the vascular segments, producing elongation and dilatation of the vascular wall, resulting in varicosities and sacculations. Change to malignancy is not common.

The naevus vinosus (portwine birthmark, naevus flammeus) is at times classed with the hemangiomas but is different in structure. These growths are really telangiectases containing varying amounts of pigment. Present at birth, they rarely undergo progression. They are not amenable to treatment, although improvement occasionally results after quartz water cooled ultra-violet irradiation. Cosmetic preparations are gen-

vein sclerosing therapy to hemangiomas. He used a 5 per cent aqueous chloral hydrate solution. deBarnes of France employed 25 per cent quinine hydrochloride and 25 per cent antipyrine solution in 1927. Augé and Cotsaftis² in 1928 had success with quinine hydrochloride and ethyl carbamate (urethane). S. E. Light,³

Fig. 3.—Sloughing hemorrhagic hemangioma of the labia majora: *A*, appearance when infant was 3½ months old. Three treatments were given during the subsequent six months. *B*, appearance at 15 months, one-half year after last injection.

Fig. 2.—Sloughing hemangioma of neck: *A*, at age of 7 months. Subjected to four treatments during following three months. A small lesion of the left upper eyelid can be discerned. *B*, lesions when child was 14 months old. The lesion of the eyelid was subjected to two cautious injections.

erally advocated to cover the blemish, treatment directed toward eradication usually being futile.

Diffuse, irregular, flat, pale red areas of telangiectases are commonly observed at birth over the nape of the neck, over the occipital scalp, over the midfrontal area and about the nose. When compressed they blanch; with crying, their color is intensified. These usually regress spontaneously without treatment.

The common methods of treatment of hemangiomas advocated by textbooks are not practical for ordinary use. Though detected early, treatment of the lesions is often held in abeyance. Electrical desiccation, refrigeration with carbon dioxide snow, heat cauterization, chemical cauterization (phenol or nitric acid) and curettage are all drastic measures producing sloughing and not infrequently unsightly scar or keloid formation. Radium treatment is costly. Because of their common occurrence in pediatric practice, a simple method of treatment, available to the average physician, was sought and has proved most successful in my hands.

Juaristi,¹ a Spaniard, appears to have been the first to describe his application in 1925 of the recent varicose

of Tacoma, Wash., reported a case in 1931 treated successfully with injection of 30 per cent sodium salicylate and invert sugar solution. Andrews and Kelly⁴ in 1932 used 20 per cent quinine hydrochloride and ethyl carbamate, sodium chloride and 50 per cent dextrose solutions with success. No untoward effects are mentioned in their reports.

The injection treatment of hemangiomas can be employed in office practice or clinics inexpensively and with excellent ultimate results comparable to or superior to other methods generally used. After trial of several solutions, 20 per cent quinine dihydrochloride and urethane diluted with an equal part of

Fig. 4.—Typical hemangioma of the thigh: *A*, appearance when girl was 10 months old. Three treatments were given during the next three months. *B*, appearance at 20 months, seven months following last treatment.

2 per cent procaine hydrochloride (with epinephrine) was found painless and most effective. The subjects were largely infants. The procedure was the injection

through a 26 gage short bevel security type hypodermic needle along radial paths from a single injection site. This needle has a metal bead incorporated in the shaft adjacent to its attachment to the hub. It allows the needle to be easily retrieved if broken. A half cubic centimeter vaccine or tuberculin syringe allows accurate control of the solution injected. The needle is so

puncture. If the lesion is very irregular in outline or its diameter is greater than the length of the needle chosen, other injection sites may be chosen. A small gauze pad is applied firmly over the entire injected area with adhesive tape. The dressing is removed after from forty-eight to seventy-two hours and the area left exposed. If too much solution has been injected there may be central sloughing, but these areas generally heal uneventfully although more ultimate scarring results. A month after the initial treatment the lesion should be blanching satisfactorily or there may remain scattered areas of angioma which are beginning to grow afresh. These are then injected individually and after another month has passed one observes that there appears no longer a tendency for growth and that the mass is being replaced by a glistening naturally colored or light brownish epidermis, which in time, according to the area involved and the age of the subject, becomes

Fig. 5.—Section of hemangioma hypertrophicum.

directed that the solution is initially injected superficially throughout the mass. From 0.1 to 0.2 cc. is injected at a time. Immediate blanching of the area occurs about the needle point. The needle is then advanced and the next injection is placed so that its area of blanching is contiguous with the previous one.

Fig. 6.—Section of hemangioma cavernosum.

Multiple areas are thus injected until the entire lesion has been mottled with areas of blanching. The point chosen for injection often bleeds, but a few minutes pressure with gauze or a drop of collodion will seal the

Fig. 7.—Highly vascular section of a cavernous lesion under high power.

inconspicuous. It is at times necessary to inject more deeply into the mass if it is quite elevated after the superficial portion has been dealt with. In small hemangiomas of the papillomatous type one may observe complete blanching of the mass with one injection into the base if the injected solution chanced to flow into the afferent vessel. From one to six treatments may be necessary.

Forty-four hemangiomas in thirty subjects have been treated as described, all with excellent ultimate results. The ages were from 2 weeks to 3 years. There were no systemic reactions. A few sloughs occurred in my early experience, but these healed without significant extra scarring. The lesions have varied in size from 1.5 to 38 mm. They have involved the scalp, forehead, eyelid, auricle, lips, chin, cheek, neck, torso, genitalia, all parts of the extremities, and the buttocks. Several were sloughing spontaneously and infected before treatment was started. There were no recurrences after from two to four and one-half years.

With such relatively safe, simple, effective and inexpensive a form of treatment, vascular nevi should not be allowed to achieve any appreciable size. Treatment of very extensive and complicated lesions involving

deeper tissues should not be attempted by this method. Radium treatment is then more practical and effective.

Photographic illustrations of a few of the more severe lesions before and after treatment are reproduced.

CONCLUSION

Strawberry birthmarks (hemangioma cavernosum) and other vascular nevi are often neglected because the usual methods of treatment are unpractical, expensive, or require special knowledge or equipment.

A simple method of injecting sclerosing solution to obliterate these nevi has been developed.

The results of the injection method of treatment of selected lesions compares favorably with, or is superior to, other methods.

Its simplicity is conducive to preventive treatment and therefore provides an effective means of obliteration of birthmarks, available to any practitioner.

RUPTURE OF AN AORTIC ANEURYSM INTO THE PULMONARY ARTERY

REPORT OF A CASE

MAHLON H. DELP, M.D.

AND

ROBERT MAXWELL, M.D.

KANSAS CITY, KAN.

Aortic aneurysm, always an interesting clinical and pathologic condition, is fairly common. However, an aortic aneurysm which ruptures into the pulmonary artery remains sufficiently unusual to warrant this brief report.

Perforation of a thoracic aneurysm into blood vessels of the thorax is not particularly frequent, and rupture into the pulmonary artery is still less frequent. Thurman¹ in 1840 published the first important discussion on this subject, outlining the clinical features of abnormal communication between the aorta and the pulmonary circulation. Discussions of the clinical picture, case reports and summaries of cases previously recorded have been published by Kappis,² Peacock,³ Taylor,⁴ Korb⁵ and Potter.⁶ A case report has appeared in the Italian literature and another in the French literature during the past two years.

Stevenson⁷ found only three such cases in a series of 3,900 autopsies performed in the Johns Hopkins Hospital. Boyd⁸ reported forty-five in a total of 1,197 cases of ruptured aneurysm. This series was collected in a comprehensive study of the literature. Lemann⁹

collected 592 cases of ruptured aortic aneurysm, in eighteen of which the aneurysm had ruptured into the pulmonary artery. It seems likely that some of the cases reported by Boyd were included in Lemann's series. Potter, in a case report appearing in 1934, said that he had been able to find only fifty-four authentic accounts of this pathologic anatomic rarity. In his series of 1,726 autopsies at St. Luke's Hospital, Chicago, he saw only six thoracic aneurysms, an incidence of 0.35 per cent. Of these, three had ruptured into the superior vena cava and another into the pulmonary artery. In a series of 6,099 autopsies at the University of Kansas Hospitals between 1914 and 1936, eighty-two thoracic aneurysms were observed. Forty-six had ruptured, only one into the pulmonary artery.

REPORT OF CASE

History.—W. M., a Negro man, married, aged 40, an electric crane operator, was admitted Dec. 30, 1935, to the medical service of the University of Kansas Hospitals. His chief complaints were shortness of breath, pain in the chest and rapid heart action. The family history was not significant. The patient's first wife had eight pregnancies, two ending in miscarriages. No details were available concerning these. Six children were living and well. The second marriage was of two years' duration, and there had been no pregnancies. The patient had used no alcoholic beverages, did not use tobacco and seldom drank tea or coffee. He had suffered the usual childhood diseases, including measles, mumps and frequent attacks of tonsillitis. A vague history of joint pain, involving chiefly the hip joints, at approximately the age of 18 could not be interpreted as rheumatic fever. The patient said that he had not had a syphilitic infection; however, he had had gonorrhea. An automobile accident eight years before had resulted in an injury to the left leg which necessitated amputation just above the knee. The patient had engaged in the usual activities without any unusual symptoms until the onset of the present illness. Previous to the amputation of his leg he had enjoyed athletics and had played baseball on several amateur teams. Until five months prior to hospitalization he had worked regularly as an electric crane operator, and after that he had continued to work at irregular intervals until the onset of his acute symptoms. He had lost 21 pounds (9.5 Kg.) in weight during the past five months. This loss no doubt was occasioned by the failure of his appetite and his gastric distress.

Fig. 1.—Appearance of the chest.

Seven months before hospitalization, while digging a cellar at his home, the patient for the first time noted moderate shortness of breath. His complaints, then made known to the family, were not considered serious. He continued to work for about two months before taking a vacation. During his vacation his shortness of breath on exertion became more serious, and on several occasions he complained of severe pressure beneath the sternum and in the precordial region. After returning from his vacation he resumed work, but his symptoms were progressive. Frequent gastric upsets, with indigestion, nausea and vomiting, led him to try the usual home remedies, but without relief. An attack of paroxysmal dyspnea associated with severe substernal pressure pain radiating to the back seized him just three weeks before he was hospitalized. This attack followed immediately after a meal and was interpreted as another gastrointestinal difficulty; consequently

medical attention was not sought. Similar minor episodes happened frequently during the next few days. Orthopnea was a negligible symptom. At no time did the patient note edema of his lower extremity or complain of the typical anginal type of pain, with radiation down the left arm.

He sought medical attention for the first time and was seen in the outpatient department. Here he was given digitalis, and during the following week he took fifteen 1½ grain (0.1 Gm.)

Fig. 2.—Abnormalities in form of waves noted December 31.

tablets of this drug. On his return, since no improvement whatever was noted, he was immediately hospitalized.

Examination.—The patient, who was fairly well nourished and well developed, lay in bed with an expression of apprehension and an appearance of shock. He was dyspneic, very restless and perspiring profusely.

The pupils were small and irregular. They reacted fairly well to accommodation but showed no reaction to light. The ears, throat and nose were normal. The upper teeth were artificial and the lower much repaired. Adenopathy was not present in the neck. There was slight pulsation of the vessels in the neck. The thyroid was not enlarged. The respirations

were labored but regular, and the respiratory rate was 30. The vocal and the tactile fremitus were not considered abnormal. Moderate dullness over the base of both lungs was noted. The diaphragmatic excursion was normal. Numerous moist rales could be heard over the base of both lungs posteriorly.

On examination of the heart a heaving diffuse apex beat was heard. A definite short systolic thrill was palpable over the base. By percussion the heart was found to be enlarged 2 cm. to the left of the midclavicular line, and dullness extended to just beyond the right sternal border. In the pulmonic area dullness extended upward and laterally, suggesting a dilated pulmonary conus. By auscultation, a loud, harsh machinery-like systolic murmur and a soft diastolic murmur were heard best at the fourth left interspace. This murmur, however, was transmitted over the entire precordium. It was not to be

heard in the vessels of the neck. The blood pressure was 144 systolic, 64 diastolic. The pulse was regular and rhythmic, the rate being 94.

There was definite tenderness in the upper right quadrant of the abdomen, with moderate rigidity. Neither the liver nor the spleen nor the kidneys were palpable. The peripheral vessels of the extremities did not evidence sclerosis. The extremities were cold and clammy. There was no clubbing of the fingers and no cyanosis. The stump of the left leg was rough and scarred but well healed. The right leg showed no anomalies of development and no edema. The patellar reflex was not elicited. The remaining reflexes were normal.

The urine gave an acid reaction, had a specific gravity of 1.030 and contained a faint trace of albumin. There were from 4 to 5 pus cells to a high power field and no casts. Examination of the blood showed 6,150 white cells, 84 per cent hemoglobin and 66.6 mg. of nonprotein nitrogen, 0.7 mg. of creatinine and 197 mg. of sugar per hundred cubic centimeters. Subsequent examination showed 134 mg. of nonprotein nitrogen, 5.5 mg. of creatinine and 100 mg. of sugar. The Wassermann and the Kahn reactions were 4 plus.

In a 6 foot roentgenogram of the chest taken December 24 (fig. 1), the cardiac shadow measured 18.5 cm. in the greatest transverse diameter; one-half the inside diameter measured 15.5 cm. These measurements indicated that the heart was well over the normal limits in size. The hypertrophy was primarily on the left side. There was a prominence on the upper part of that side due to the pulmonary conus. No evidence of intrinsic pathologic changes in the lungs or of decompensation was seen. The aorta was narrow. No evidence of rib erosion was visible. Fluoroscopic examination showed that the left auricle was displaced posteriorly a little. A differ-

Fig. 3.—Drawing of specimen, showing aneurysmal sac with perforation into the pulmonary artery.

ential diagnosis had to be made between a pulmonary conus thrown into silhouette by an enlarged left auricle and primary hypertrophy of the conus. It seemed to us that mitral involvement with the changes described on the left side would have caused more hypertrophy on the right side than was seen. The possibility of a patent duct of Botallo had to be seriously considered.

An electrocardiogram made December 28 (fig. 2) showed right axis deviation. The QRS, which was widespread, notched and bizarre, measured 0.14 second. The PR interval measured 0.21 second. T_2 and T_3 were diphasic. Left ventricular extrasystoles were seen in lead 3. The sound record showed a machinery-like murmur, with accentuation in the systole and heard best at the pulmonary area. An impression was given of organic myocardial damage, with strain on the right ventricle or failure of the left ventricle. On December 31 the rate averaged 130. An electrocardiogram showed that the waves were greatly changed. The QRS was spread to 0.16 second. The T and the P waves were apparently together. The sound record showed a machinery-like murmur, as before. An impression was given of organic myocardial damage, with a changing form of ventricular complex.

Course.—After the patient's admission he grew progressively worse, responding to no type of therapy. He was restless and apprehensive, had a distinctly subnormal temperature and perspired profusely. For the twelve hours preceding death he had a very slow, weak pulse and it was impossible to get an accurate measurement of the blood pressure. He died approximately forty-eight hours after admission.

The x-ray examination, coupled with the examination of the heart, led to a possible diagnosis of congenital heart disease with a patent ductus arteriosus. The history gave little credence to such a diagnosis. The positive serologic reactions and the appearance of the pupils led to a clinical diagnosis of syphilitic heart disease, the true nature of which was suspected.

Autopsy.—This was performed eight and one-half hours after death. When the thoracic cavity was opened 300 cc. of clear fluid was observed on the left side. The pericardial sac contained 150 cc. of a serosanguineous fluid and many petechial hemorrhages, together with a thin fibrinous exudate. The heart was globoid and enlarged, weighing 750 Gm. Several milk patches were noted over its pericardial surface. The walls of the ventricles were hypertrophied, the left measuring 2 cm. and the right 8 mm. in thickness. The valvular rings and the cardiac chambers were all dilated. The tricuspid valve measured 14 cm. in circumference and the mitral valve 12 cm. The coronary arteries were patent and showed no evidence of sclerosis.

The ascending aorta was irregularly dilated, measuring 12 cm. in circumference at its widest portion, which was 4 cm. above the aortic ring. A few small sacculations could be seen in the ascending portion. Approximately 4 cm. above the aortic valve there was a slitlike perforation about 2 cm. in length in the wall of the aorta (fig. 3). The margins of this opening were rough, jagged and covered with fibrin and blood, communicating directly with the lumen of the left pulmonary artery about 3 cm. before its bifurcation. The wall of the aorta in this region was thin, and its external surface was covered with a grayish exudate. The intima of the arch of the aorta showed atheromatous plaques and distinct longitudinal wrinkling and puckering throughout its length. The aneurysm involved the ascending aorta and part of the aortic arch. The following circumferences give some idea of the size of the aorta: ascending portion 12 cm., transverse portion 8.5 cm., and descending portion 5 cm.

Microscopic examination of sections from the aortic arch revealed a typical picture of syphilitic mesaortitis, with a thickening of the vessel walls in the media and a perivascular infiltration of mononuclear cells. Irregular puckered scars were scattered throughout in the region of the vasa vasorum. The heart muscle itself showed some fragmentation and segmentation of the muscle fibers, with an increased amount of fibrous tissue scattered throughout the myocardium. The lungs showed evidence of edema and chronic passive congestion. The other organs showed no significant pathologic changes.

The cause of death, from the anatomic standpoint, was evidently cardiac failure brought about by an unusual complication associated with syphilitic mesaortitis. The ascending arch of the aorta showed fairly characteristic syphilitic changes, and a beginning aneurysm formation ruptured near the root of the aorta into the first portion of the pulmonary aorta, producing

an artificial fistulous connection between the two aortas and a condition that is similar to patent duct of Botallo. These conditions could account for the unusual clinical observations.

COMMENT

Articles written by Kappis,² Taylor⁴ and Scott¹⁰ contain a most complete and definite clinical picture of the symptoms and signs of aortic aneurysm rupturing into the pulmonary artery. If this picture was kept well in mind, a diagnosis no doubt could be made. While the rupture of an aortic aneurysm is as a rule promptly fatal, perforation into the pulmonary artery frequently is not. This was true in our case. It is not unreasonable to assume that our patient had had practically all of his pathologic changes since three weeks before hospitalization, the date of the onset of his acute symptoms.

In reviewing the salient features of the clinical course and the physical examination in reported cases we find that the onset is always abrupt and usually follows exertion. Severe substernal pain, anginal in character, leads frequently to a diagnosis of coronary occlusion. A feature noted in practically every case is breathlessness, with marked apprehension and evidence of shock. Severe cough and edema of the lower extremities are frequent, although neither was present in the case reported. As a rule the clinical course is that of progressive circulatory failure, death occurring in a few weeks or at most a few months.

Rupture into the pulmonary artery creates an arteriovenous aneurysm, the physical signs of which are easily interpreted. The similarity of the picture to that of the congenital anomaly patent ductus arteriosus is evident. A characteristic physical sign is a continuous machinery-like or humming-top type of systolic murmur, heard loudest over the pulmonic area and transmitted over the entire precordium. A systolic thrill, noted in the region of the murmur's greatest intensity, is often palpable. Both of these signs were definite in the case reported. A diastolic murmur at the third left interspace is common, and so is accentuation of the second pulmonic sound. Cyanosis, distention of the veins, and edema of the face and neck are not always present. It is not always possible to elicit signs of an aneurysm, because the sac is frequently small and does not project beyond the base of the heart. X-ray studies frequently do not aid in the diagnosis. In our studies, roentgenograms of the chest revealed only what appeared to be a dilated conus, lending support to a diagnosis of congenital heart disease. The possibility of this condition presents the major differential problem. In our case the preponderance of evidence favored syphilitic aortitis, with aneurysmal involvement making the diagnosis of congenital heart disease unlikely.

The Fifty-Nine Millionth Year of Primate Life.—Our first absolute proof of the existence of man upon the earth occurs about at the completion of the fifty-nine millionth year of primate life, just before the onset of the great glacial period. Stone implements, very crudely chipped, but evidently fabricated by human hands, afford mute evidence that our ancestors were in existence, at work, and apparently making a rather poor job of it. It is not until the first quarter or possibly the first half of the million year glacial period has elapsed that we actually find the bones of man.—Hooton, E. A.: *Apes, Men, and Morons*, New York, G. P. Putnam's Sons, 1937, page 275.

MERALGIA PARAESTHETICA

A REPORT OF ONE HUNDRED AND FIFTY CASES

ARTHUR D. ECKER, M.D.
Fellow in Neurology, the Mayo FoundationAND
HENRY W. WOLTMAN, M.D.
ROCHESTER, MINN.

In 1895 Bernhardt¹ directed attention for the first time to a curious condition, marked by numbness, on the anterior and especially on the outer surface of one thigh, which became relatively painful only after prolonged exertion or on pressure on the abnormally sensitive regions. In the cases that he reported there was no history of bouts of pain which occurred spontaneously during rest. Shortly afterward Roth² gave the disease its formidable title, "meralgia paraesthetica," from the Greek words *meros* (thigh) and *algos* (pain). It is our purpose in this paper to review the present status of this disease and to analyze the clinical observations on a series of cases that have been studied under standard conditions for a moderately long time.

MATERIAL

Our study was directed to the records of 150 cases of meralgia paraesthetica observed at the Mayo Clinic. The incidence of this condition among patients observed at the clinic in the period covered by this study was 0.035 per cent, or about three in 10,000. This figure can be compared with 0.94 per cent, or 4,293 cases of sciatica, and with 1.16 per cent, or 5,316 cases of other forms of peripheral neuritis recorded during the same period.

ANATOMIC CONSIDERATION

The lateral femoral cutaneous nerve is entirely sensory and is derived from the posterior roots of the second and third lumbar nerves on the corresponding side. After emerging from the lateral aspect of the psoas major muscle, the nerve crosses the iliacus muscle and continues toward the anterior superior spine of the ilium by turning upward sharply from the deep circumflex iliac vessels and passing beneath the fibrous attachment of the internal oblique muscle of the abdomen. It usually continues medial to the anterior superior spine of the ilium and under the inferior portion of the inguinal ligament but may pass under or even lateral to the origin of the sartorius muscle.³ As it emerges from the pelvis there occurs a marked angulation of the nerve which is increased by extension and lessened by flexion of the thigh.⁴ The nerve passes inferiorly and, about 4 cm. below the inguinal ligament, it pierces the fascia lata; the arcuate fibers of this fascia tend to protect this nerve from compression. The main or anterior branch remains beneath the fascia of the thigh, becomes superficial about 9 cm. below the inguinal ligament and supplies the skin of the thigh down to the knee. The small posterior branch soon becomes superficial and supplies the skin from the greater trochanter down to the area supplied by branches from the anterior division.

ETIOLOGY AND PATHOGENESIS

The numerous theories that have been proposed to explain the origin of this disease can be divided into those which consider it an evidence of a generalized toxic or infectious process and those which regard it as of local origin. It may well happen that the two act together. This is clearly illustrated in ulnar neuritis and peroneal neuritis, which may develop during the later stages or after an attack of typhoid. The neuritis usually has been attributed solely to selective toxemia, but the factors of loss of weight and local pressure are probably of greater importance.⁵

Distribution According to Age.—Because the symptoms of meralgia paraesthetica may persist for years, it seemed advisable to consider the ages of the patients at the time they first came to the clinic. At the extreme ages were two patients aged 15 years and three patients aged 65 years. Four patients were in the second, nineteen were in the third, thirty-five were in the fourth, forty-four were in the fifth, thirty-five were in the sixth and thirteen were in the seventh decades of life, respectively. Meralgia paraesthetica therefore starts in middle age.

Distribution According to Sex.—Of the 150 patients in our study, 111, or 74 per cent, were males, and thirty-nine, or 26 per cent, were females; therefore the ratio of males to females was 2.8:1. A study of the clientele of the Mayo Clinic as a whole revealed that the ratio of males to females was 1.04:1.⁶ It therefore is clear that meralgia affects males about three times as frequently as it affects females.

GENERAL CAUSES

The array of infectious diseases and toxic conditions which have been associated with meralgia can be found in the former reviews on the subject.⁷ However, no one of these conditions, such as diabetes or a focus of chronic infection, has been present appreciably enough in our series of cases to be considered a specific causative factor.

Obesity.—Roth observed that meralgia was most frequent among those who are somewhat obese. The average weight of 136 of our patients, estimated at the onset of the meralgia, was 175.1 pounds (79.5 Kg.). This is clearly in excess of the average weight of middle-aged men and women, as determined by a standard weight chart. Although these figures are not statistical proof that obesity is causally related to meralgia, the association of the two conditions is suggested and is given further support by the following facts: Three patients gained about 15 pounds (6.8 Kg.), and eight patients gained 20 or more pounds (9 Kg.) at the time that the symptoms of meralgia began.

When posture, which is not dependent on weight but on its distribution,⁸ is altered by obesity, it must make greater demands on the inguinal ligament and fascia of the thigh. As a result, these structures may compress the nerve in its fascial bed at the anterior superior spine of the ilium, or the panniculus may exert traction on the nerve.

LOCAL CAUSES

Analogous Conditions.—Neuritis which affects an isolated sensory nerve is distinctly uncommon. The first so-called sensory mononeuritis clearly described in the literature is the very subject of our discussion. However, involvement of the superficial branch of the radial nerve at the wrist was described by Wartenberg⁹ in 1932; involvement of the external inferior cutaneous branch of the musculocutaneous nerve was described by Gordon¹⁰ in 1909; involvement of the medial femoral cutaneous nerve was described by Escat¹¹ in 1895 and by Remark¹² in 1900; involvement of the greater saphenous nerve was described by Ballet¹² in 1896 and by Kutner¹² in 1905; an involvement of the superficial peroneal nerve was described by Kutner in 1905. In none of these reports was a clear cause designated, but it is interesting to observe how frequently local causes were mentioned; for instance, Wartenberg, in attempting to explain neuritis of the superficial branch of the radial nerve at the wrist, which he designated "cheiralgia paraesthetica" because of its apparent similarity to meralgia paraesthetica, suggested the pressure of a wrist-watch band as the cause in two of his three cases. Gordon expressed the opinion that the condition he described might well have been caused by irritation of the nerve by the supinator longus muscle.

Lesions Within the Spinal Canal or Intervertebral Foramina.—The factors that might affect the nerve locally may now be subdivided. In our series there were five cases in which the primary lesion apparently affected the nerve roots within the spinal canal. In two of these cases the condition was diagnosed as multiple sclerosis. In the third case the meralgia was a residuum of radiculitis. In the fourth case the illness had begun with empyema thoracis, which had been followed by a perinephric abscess and then by an osteitis of the second and third lumbar vertebrae. Laminectomy revealed arachnoidal adhesions, which were freed. When the patient returned to the clinic nine years later he did not complain of meralgia. In the fifth case acute bilateral meralgia paraesthetica developed shortly after the use of spinal anesthesia. Intermittent spasms of the tensor fasciae latae muscle were associated with the meralgia. Three months later the inner aspects of the thighs, as well as the outer, became anesthetic and painful at night and when the patient was on his feet. In 1925 Rosenheck¹³ stated his opinion that meralgia paraesthetica is the expression of a radicular syndrome secondary to osteo-arthritis of the spinal column. He also said that in practically all his cases there was definite roentgenologic evidence of an osteo-arthritic process.

In an effort to shed light on this question, we reviewed the roentgenologic studies in the eighty-three cases in which roentgenograms had been made of the lumbar vertebrae. This review disclosed normal lumbar vertebrae in thirty-eight cases, hypertrophic arthritis of the lumbar vertebrae in twenty-five cases, spina bifida occulta in seven cases, scoliosis of the thoracolumbar vertebrae in four cases (two of these

cases are included under hypertrophic arthritis), local changes of the second and third lumbar vertebrae in four cases (one of these cases is included under spondylolisthesis), sacralization of the fifth lumbar vertebra in two cases, spondylolisthesis of the fifth lumbar vertebra on the sacrum in two cases, calcified proliferation of the lumbosacral intervertebral disk in two cases, osteitis deformans of the ilium in one case and old trauma of the fourth and fifth lumbar vertebrae in one case.

In one of the four cases in which local changes were found in the second and third lumbar vertebrae there was infectious destruction of the disk between the second and third lumbar vertebrae, and the density of these vertebrae was increased. In the second case there was evidence of an old fracture of the upper anterior margin of the third lumbar vertebra. In the third case there was evidence of an injury of the first three lumbar vertebrae and marked compression of the second lumbar vertebra. There was also the appearance of superimposed Charcot joint of the spine. In the fourth case there was a congenital deformity of the right lateral articular facet of the third lumbar vertebra. The meralgia also was on the right side.

Spina bifida occulta was found in 8 per cent of our cases, but this percentage is negligible.¹⁴ The spina bifida was not situated above the fifth lumbar vertebra in any of these cases. Roentgenologic examination will not disclose the cause of meralgia unless the disease is associated with trauma or infection that is localized in the second and third lumbar vertebrae.

Intra-Abdominal and Intrapelvic Conditions Which May Affect the Lateral Femoral Cutaneous Nerve.—It will be recalled that the lateral femoral cutaneous nerve runs retroperitoneally across the iliacus muscle after emerging from the lateral aspect of the psoas major muscle. The nerve passes near the cecum and the appendix and is liable to involvement by lesions arising from these sources.¹⁵ In one of our cases rapid abdominal enlargement, which was partly the result of diffuse hepatic cirrhosis and partly the result of ascites of hepatic cirrhosis, was associated with the onset of meralgia.

Pregnancy is occasionally associated with meralgia but probably exerts its effects by tension on the abdominal fascia rather than by direct pressure on the nerve. In three of our cases the onset of the meralgia was associated with pregnancy. In one of these cases the meralgia had appeared in association with a lumbosacral palsy which had occurred when the patient had given birth to a child. Continual burning and tingling in the anterolateral aspect of the right thigh had persisted for nineteen years. Division of the nerve below Poupart's ligament produced relief.

Injury of the Nerve as It Passes Through the Fascial Canal in the Upper Part of the Thigh.—In five cases in our series the etiologic agents apparently were peripheral. In the first of these cases the meralgia had occurred after the patient had fallen on the thigh in a bathtub; in the second case a definite "snapping" in the thigh had occurred when the patient had raised a pickax; in the third case the meralgia had been present

since tetanus antitoxin had been injected into the thigh some years before the patient came to the clinic, and in the fourth case it had followed an injection of quinine into the fascia lata. In still another case the meralgia had occurred suddenly while the patient was carrying a sewing machine downstairs.

Abdominal Compression.—The wearing of trusses, belts and corsets has been implicated as an etiologic agent since the original description by Bernhardt. The first case that he reported occurred in an army officer whose meralgia was aggravated by wearing a belt and then was aggravated further by a sword which dangled from the belt. Abdominal compression apparently was the cause of the meralgia in four of our cases; three of these patients had worn a truss for hernia, and in one case the patient had worn a sacroiliac belt for sciatica.

In ten cases in our series the meralgia occurred after the patient had undergone an operation. In some of these cases it is possible that the meralgia was caused by an abdominal binder. The following operations were performed: nephrectomy in two cases, appendectomy in two cases, exploratory laparotomy for duodenal ulcer in two cases, herniorrhaphy for diaphragmatic hernia in one case, cholecystectomy in one case, hysterectomy in one case and radical mastoidectomy in one case. In two of these cases transitory numbness had been present before operation; these were the only cases in which there was any suggestion that the meralgia had been latent before the operation. In most of the cases in which the meralgia occurred after an operation the discomfort cleared up promptly.

SYMPTOMS

The disease is usually unilateral; one side is affected as frequently as the other. The right side was affected in fifty-four (36 per cent) and the left side was affected in fifty-seven (38 per cent) of the cases. Even when the disease is bilateral, as it was in thirty-three cases (22 per cent), it usually does not begin so. In more than 50 per cent of our cases symptoms had been present for one or more years before the patients came to the clinic. The duration of symptoms was as follows: less than one month in seven cases, from one to nine months in thirty-eight cases, from one to four years in thirty-nine cases, from five to nine years in twenty-two cases, from ten to nineteen years in thirteen cases, from twenty to twenty-nine years in six cases, and from thirty to thirty-five years in three cases. In twenty-two cases the duration of symptoms was not specified. Numbness was the most common and frequently the earliest symptom; it occurred in 115, or 77 per cent, of the cases. The following subjective sensations also were recorded: tingling in 34 per cent, pain in 24 per cent and burning in 23 per cent of the cases. Appreciation of touch, pain and temperature was diminished in 68 per cent of the cases, but appreciation of pressure was not lost in any case.

Bernhardt originally noted that numbness was a constant symptom and that tingling, burning and pain occurred only after prolonged standing. In our series of cases this feature was common enough to be characteristic. In only two or three cases was the pain aggravated when the patient was sitting or lying down.

Before the accurate clinical description of meralgia, its differential diagnosis was more of a problem than it is today. It is apparent that involvement of the lateral femoral cutaneous nerve may be the first sign

of neurosyphilis and other intraspinal and vertebral lesions. In the typical and particularly the more chronic forms of meralgia there should be no difficulty in making the diagnosis.

PROGNOSIS

In most of our cases, no specific treatment for the meralgia was required. However, records of twenty-nine patients who were examined at varying intervals, averaging two years from the time the original diagnosis was made, showed the following facts: Complete or almost complete relief of pain occurred in eighteen cases; slight or moderate relief occurred in two cases, but no relief occurred in nine cases. The previous duration of symptoms in most of the eighteen cases in which complete or almost complete relief was obtained was less than two years. In other words, when the symptoms have lasted less than two years, the chances are two to one that they will disappear spontaneously within another two years.

TREATMENT

An offending belt or truss should be removed or correctly padded so as not to press on the nerve. When the onset of symptoms is related to obesity, reduction of weight should be advised. Numerous other therapeutic maneuvers have been recommended. Bernhardt, for instance, recommended lukewarm baths, massage and electricity.

Occasionally the symptoms demand active treatment. In these instances resection of the nerve or neurolysis is advisable. Presumably the first surgical measure used to relieve the condition was resection of a portion of the lateral femoral cutaneous nerve, in 1885, by Hager.¹⁶ Resection of the nerve is now the standard operation for the condition, and the result usually is completely satisfactory. Stookey modified the original operation to simple severance of the nerve; he allowed the separated ends to remain in place and anticipated that regeneration would bridge the gap and restore sensation. Lee objected to the possibility of the formation of a neuroma at the end of the resected nerve and to the resultant anesthesia. In one case reported by Lee, in which thorough neurolysis was performed, "slight numbness and a little pain over the area involved" occurred on the seventy-third day after operation; it therefore is clear that neurolysis is not always satisfactory.

SUMMARY

Meralgia paraesthetica is a neuritis of the lateral femoral cutaneous nerve which is caused usually by pressure or tension of the overlying fascia, but occasionally it is caused by other factors. Its incidence is about a thirtieth that of sciatica and that of all other forms of neuritis. It most commonly affects obese, middle-aged men and usually begins as a sense of numbness over the anterolateral aspect of one thigh. Later to the numbness are added the sensations of burning, tingling and pain, which are aggravated by standing or walking. Both thighs may be affected. Usually there can be found slight loss of appreciation of light touch, pain and thermal sensation in the affected area. It is important to recognize the condition in order to exclude the presence of a specific causative factor and then to reassure the patient that the discomfort is usually self limited and that, if necessary, it can be relieved by simple severance or resection of the lateral femoral cutaneous nerve.

VENEREAL LYMPHOGRANULOMA

WILHELM FREI, M.D.

NEW YORK

The old school of medicine distinguished four separate diseases which are now combined into the picture of venereal lymphogranuloma: 1. The so-called strumous or scrofulous bubo, known especially to the European venereologists and related particularly to tuberculosis or chancroid. 2. The so-called climatic bubo, known to tropical and naval physicians and associated by most of them to the climate of the tropical countries. These physicians did not know the existence of the strumous bubo, and the venereologists in turn were not aware of the climatic bubo. 3. The so-called esthiomene, a kind of chronic ulcer and elephantiasis of the vulva related by most of the earlier venereologists and gynecologists to cancer, tuberculosis or syphilis. 4. The so-called inflammatory rectal stricture related by surgeons to gonorrhea, syphilis or other diseases. Esthiomene and rectal stricture frequently appeared in the same patients, but the gynecologists usually noticed only the esthiomene and the surgeons only the rectal stricture.

Later some pioneers made valuable contributions. Brault¹ was of the opinion that strumous bubo and climatic bubo might be the same disease. Rost,² a naval medical officer, observed that the midshipmen who went ashore in tropical ports under supervision never contracted climatic bubo but that the older marines who went alone did; therefore he suspected this bubo to be not of climatic but of venereal origin. Friedrich Koch,³ an early pupil of Jadassohn, maintained the existence of a relationship between esthiomene and bubo, and Dr. Jersild⁴ of Copenhagen established the connection between rectal stricture, esthiomene and lymphatic glands.

The series of discoveries in the disease has developed in four steps. In 1913 the French scientists Durand, Nicolas and Favre⁵ proved that the so-called strumous bubo is a separate venereal disease and in the next year two German physicians, Müller-Meernach and Justi,⁶ proved the same for the climatic bubo. Durand, Nicolas and Favre introduced the unfortunate name lymphogranulomatosis inguinalis subacuta, but I shall not discuss the question of nomenclature here. I will merely state that venereal lymphogranuloma is not related to granuloma inguinale, another venereal disease consisting of chronic luxuriant ulcers produced by Donovan's bodies.

The second step was my finding of a specific skin reaction, the so-called venereal lymphogranuloma skin test, 1925.⁷ With the help of this test the identity of venereal lymphogranuloma and of climatic bubo were proved and abortive and inapparent forms of the disease were brought to light. Besides, together with Alice

Koppel, I found the relationship of esthiomene and rectal stricture with venereal lymphogranuloma.⁸

The third step was the transmission of the disease to animals, especially through intracerebral inoculations of monkeys, by the Swedish scientists Hellerström and Wassén in 1930.⁹ With this method they proved that the organism of the disease belongs to the group of filtrable viruses. Their work has been continued by many investigators, above all by Levaditi, who has introduced the mouse as the most suitable animal for the purpose and who was the first to demonstrate virucidal antibodies in the blood serum of infected men and animals.¹⁰

At the present time the fourth step in the investigation of the disease is in progress. It is the cultivation and microscopic examination of the virus along lines used in other virus diseases.

In America as early as 1890 an excellent clinical study of more than 100 cases of strumous bubo had been made by Klotz¹¹ of New York. In 1932 Sulzberger, Wise and Wolf,¹² as well as DeWolf and Van Cleve,¹³ introduced the venereal lymphogranuloma cutaneous test in this country, and then intensive studies began over the entire United States, starting with the works of Cole,¹⁴ Wien and Perlstein,¹⁵ and Lehmann and Pipkin.¹⁶ I am not able to enumerate all the noteworthy publications; I will merely mention the more recent experimental studies of Grace and Suskind,¹⁷ of D'Aunoy, von Haam and Lichtenstein,¹⁸ of Howard and Strauss,¹⁹ of Joseph Tamura,²⁰ of Williams and Gutman²¹ and of Rosen, Rosenfeld and Krasnow.²²

EPIDEMIOLOGY

Venereal lymphogranuloma is found in all countries and in all races, although it is more rare than syphilis and gonorrhea. As in other venereal diseases, its frequency depends on the degree of sexual promiscuity of the population; therefore a high percentage is found in metropolitan cities or seaports such as New York, Paris and Berlin, but strangely enough not in London. There is also a high frequency of the disease among prostitutes and among different colored races, for example Negroes and Malaysians, but not so much among Arabs (circumcision?). Venereal lymphogranuloma does not always follow the general curve of other venereal diseases; it has its own features, as, for instance, peculiar endemic centers and times.

A question of special importance is the distribution of venereal lymphogranuloma in the sexes. The bubo form of the disease occurs much more often in males, the elephantiasic and ulcerative form more often on the genitalia and rectum of females. It has seriously been discussed whether these elephantiasic and ulcerated forms represent an infectious stage of the disease. Most authors believe it does, but I am still not totally convinced. This question is of great epidemiologic importance, because quite a few prostitutes are affected with these incurable manifestations without discontinuing sexual intercourse for many years.

Of greatest importance in the spread of venereal lymphogranuloma is the so-called primary lesion on the genitalia, the beginning of the disease. Later on when the bubo has fully developed there is ordinarily less danger of transmission by men. Abortive and inapparent forms, which are known to exist, especially in women, offer a dangerous source of infection even for years. There are several little endemics known to have been started by one single woman who had only slightly enlarged inguinal glands and a mild discharge and gave a positive cutaneous test.

Perverted sexual intercourse also plays a role in the disease. Most rectal strictures in men are produced by homosexual infection of the rectum. Venereal lymphogranuloma of the submaxillary and related glands can occur by infection through the mouth.

Accidental infections have also been observed in some cases; for example, in children who have slept in the same bed with infected adults, and in surgeons who have contracted the disease in the axillary glands after the excision of buboes.

CLINICAL PICTURE

Venereal lymphogranuloma begins with an average incubation of from ten to twenty-five days but occasionally after a period of some months. In a large number of cases the first sign is a small lesion at the portal of entry, generally the genitalia, the so-called lymphogranulomatous chancre, usually not noticed by the patient. The examining physician often finds these lesions or their residua when the patient consults him on account of the bubo. The bubo shows in a large number of cases an appearance similar to that of tuberculosis, with multiple foci of suppuration and fistulation. But in other cases the picture is more like an acute chancroid bubo or like a harmless looking insignificant swelling of the inguinal glands. The iliac glands often participate in the disease. In females the bubo process can develop unnoticed inside the pelvic girdle. During the extirpation of buboes in venereal lymphogranuloma, one sees that the central lymphatic vessels take part in the disease. Sometimes the peripheral subcutaneous lymphatic vessels of the genitalia also show swelling and suppuration of nodular form.

Venereal lymphogranuloma is often but not always connected with general disturbances such as fever, weakness, headaches, rheumatoid symptoms sometimes with joint swelling, rashes and conjunctivitis. Changes have been described even in the fundus of the eye and in the spinal fluid. One finds an increased sedimentation rate and a leukocytosis of moderate degree, and sometimes a transitory positive Wassermann reaction, which is important to know.

In most cases this disease extends over several months, sometimes only over a few weeks and rarely over years. A fatal termination is very rare.

The form of the disease localized in the lymphatic glands must be distinguished from the ulcerative elephantiasic form localized on the genitalia, rectum or both. The earliest sign of this form consists of small uncharacteristic ulcers on the vulva, anus or rectum or of a mild inflammation, particularly in the rectum. These ulcers may persist and enlarge, disappear and reappear. In neglected cases they can destroy the whole genitoperineo-anal area and lead to the formation of a cloaca. The ulcers occur with or without elephantiasic changes characteristic of this form of the disease.

On the female genitalia the elephantiasis consists of a swelling of moderate degree on the labia majora, sometimes labia minora, urethra or other parts. On the male genitalia one sees elephantiasis more often than ulcers. In the rectum the elephantiasis shows a characteristic rigid, often verrucose, thickening of the walls extending usually up to from 5 to 8 cm. from the anus and ending in a more or less narrow stricture of cylindric or annular form. These strictures often cause great difficulty in defecation; the feces may become pencil-like, but a complete occlusion is very rare. Involvement of the mucous membrane produces a bloody purulent viscous discharge. Involvement of the pararectal tissue causes pararectal abscesses and fistulas which break through mostly around the anus and buttocks. The anal folds often form elephantiasic round hemorrhoid-like or lobated cockscomb-like small tumors.

In some cases presenting ulcerative elephantiasis the disease does not reach its full height and spread. For example, occasionally the only sign of the disease for a long time may be a swelling and ulceration of the female urethra, a swelling of the anal folds, a chronic anal fistula, chronic abscesses on the buttocks or circumscribed elephantiasis in the rectum. On the other hand, one also finds cases presenting an extraordinarily large extension. For instance, in the intestinal tract, strictures or ulcers may extend uninterruptedly or at intervals to the transverse colon, occasionally giving the picture of ulcerative colitis.

The prognosis of the ulcerative elephantiasic form is doubtful. Many patients live for years in a tolerable state of health. Others may die earlier from secondary infections and their complications. The rectal form in general seems to be more dangerous than the genital form. Only in the first stage with early ulcers may healing occur.

Between the two forms of the disease, the bubo and the ulcerative elephantiasis, a close relationship exists. In the earliest ulcerative stage inflammatory residua of a previous inguinal bubo are often found; in the later stage characteristic bubonic scars are seen. In other cases, for example in the majority of isolated rectal strictures, every sign of a previous external bubo is missing. Like Jersild, I have believed that in these cases lymphatic changes have previously occurred in the internal glands and vessels alone, while in the other cases external as well as internal glands have been involved. Today many experts believe that the ulcerative elephantiasic changes arise by direct ascending infection of the genitalia, and especially of the rectum, without previous glandular involvement. At any rate the development of the same elephantiasic swelling in cases with and without inguinal changes demonstrates the close connection of this entire form of the disease with the lymphatic system.

DIAGNOSIS

A fully developed lymphogranulomatous bubo in the inguinal region with all characteristic signs, especially when coupled with a suggestive history, does not give rise to any doubts; but, if the bubo is in its earliest stage or has an uncharacteristic form, one must consider other diseases too; for instance, simple glandular swelling, syphilis, chancroid bubo, tuberculosis, Hodgkin's disease, lymphatic leukemia, malignant tumors or tularemia. Likewise a fully developed elephantiasis form of the female genitalia, anus and rectum with all the characteristic signs permits, according to my opinion, definite diagnosis of venereal lymphogranuloma. But if the genitalia alone or the anus alone is involved, or the disease is in a beginning or abortive or unusual form, the clinical diagnosis is not certain. Filariasis, granuloma inguinale, chancroid, syphilis, cancer, tuberculosis, actinomycosis, dysentery, ulcerative colitis and many other diseases must sometimes be eliminated.

In the diagnosis of venereal lymphogranuloma one must also consider the possibility of mixed infections, especially with other venereal diseases.

In all doubtful cases one resorts to special diagnostic methods. For diagnosis of venereal lymphogranuloma the most frequently used method is the cutaneous test. I will not speak in detail about my experiments in this test but merely mention some practical points. The material needed consists of the diluted and sterilized pus of proved, nonruptured pure buboes of venereal lymphogranuloma. One-tenth cubic centimeter is injected intracutaneously and the reaction is read after two days. In a positive case one finds an inflammatory papule of at least 0.5 cm. in diameter, often with peripheral erythema and sometimes with central pustule. In negative cases there is no or very little reaction after two days. Only tested vaccines corresponding to these conditions should be available for general use. On account of the possibility of generalized or focal reactions, it is not advisable to make the test in peracute stages of the disease or in cases in which suppuration occurs near the peritoneum.

A positive reaction does not prove that the disease still exists, because the power to react to the test remains in healed cases for decades. A negative reaction in cases of venereal lymphogranuloma occurs in the earliest stage of the bubo and in some cases in which there is transitory or constant anergy. In cases of anergy a positive result may be obtained by the so-called inverted test, in which, the patient's sterilized pus is injected into the skin of a patient with proved venereal lymphogranuloma, producing a positive reaction, or the usual vaccine is injected intravenously instead of intracutaneously into the suspect and if he has the disease he may respond by a generalized febrile reaction. It may be said that the venereal lymphogranuloma cutaneous test results in about 95 per cent of positive reactions when buboes have developed and in about 90 per cent when there is ulcerative elephantiasis.

Since the vaccine is of human origin, it is often not available in sufficient quantities, because in many of the cases there is little and sometimes no pus. Therefore some investigators have introduced vaccines of animal origin. Levaditi of the Institut Pasteur in Paris and Jonesco-Mihaiesi of Bucharest produce a vaccine from monkey brain. Grace and Suskind of New York and D'Aunoy and von Haam of New Orleans recommend vaccines made from mouse brain. Since I have had no

personal experience with vaccines of animal origin, all my present remarks deal only with the use of the original human vaccine.

In doubtful cases some results may be obtained through histologic examination. In the bubo form one finds inflammatory and suppurative changes in the glands as well as in the periglandular tissue. There is a polymorphogranulomatous tissue, tiny foci of epithelioid cells with giant cells and micro-abscesses or larger ones surrounded by epithelioid cells. The picture is similar to but not totally like that of tuberculosis. In the elephantiasis forms is found the typical picture of elephantiasis, partly connected with the changes just described.

Occasionally one can also try to confirm the diagnosis by animal experiments demonstrating the presence either of virus in the lesions or of virucidal antibodies in the blood serum.

THERAPY

There has been until now no really effective chemotherapeutic method for the treatment of venereal lymphogranuloma. I myself use antimony or gold compounds; others use also copper, iodine, or salicylic acid preparations. Only in the earliest stages or in very mild forms of bubo can one obtain abortive healing with these treatments. But one has to keep in mind the fact that some of these bubo forms have a tendency to heal without any treatment. If the bubo has grown larger, an acceleration of healing is sometimes obtained by these medications. But in severe forms of bubo as well as in elephantiasis, no definite effect is obtained by chemical treatments. The antisyphilitic remedies such as arsphenamine and compounds of bismuth or mercury usually do not give any relief in venereal lymphogranuloma. Only in a few of the cases connected with syphilis does one see improvement.

The therapeutic use of venereal lymphogranuloma vaccine had according to my experience but little effect as long as the vaccine was injected intracutaneously or subcutaneously. Since the introduction of the intravenous method by Hellerström, accelerated healing has been seen in the cases in which there are buboes and sometimes a decrease of complaints in the ulcerative forms. I have had no experience with the intravenous method, but I have seen very good results in New York, especially in the board of health department in the service of Dr. Chargin and Dr. Kornblith.

Some authors recommend the surgical method as the best treatment for the different forms of venereal lymphogranuloma. They extirpate the affected lymph glands in the early and even in the later stages; they extirpate excessive forms of elephantiasis labia majora while treating the chronic ulcerations with intensive coagulation diathermy. On the surgical treatment of rectal stricture there are two different opinions. Most physicians restrict themselves to inducing a preternatural anus as high as possible; only few prefer radical operations. In some rectal cases fairly good results can be obtained with careful, conservative treatment by very cautious dilations and mild irrigations and regulation of diet and bowel movements.

Roentgen treatment gives, perhaps, some results in bubonic cases, especially when combined with other treatment. In cases in the chronic ulcerative stages there is very little effect and in elephantiasis none. Experience with radium treatment is too limited for any conclusions to be drawn. Ultraviolet rays applied generally and locally may be tried occasionally in ulcerative elephantiasis cases.

PROPHYLAXIS

In the prophylaxis of the disease one has to distinguish between the prophylactics belonging to all venereal diseases, with which I shall not deal here, and the special prophylaxis for venereal lymphogranuloma. Primarily it is important to instruct the physicians as well as the public about the disease, its nature, its clinical features, its diagnosis and its treatment. Secondly, one has to treat infected persons as early and as thoroughly as possible, even in mild cases, in order to remove their infectiousness in the shortest possible time. Furthermore, one has to make exact inquiries in every case as to the source of the infection. Many of these infections are contracted from prostitutes. Therefore regular examination of prostitutes, especially with the aid of the cutaneous test, should be considered. Naturally, if at the first examination a prostitute gives a positive reaction, it does not prove very much, because the positive reaction can also be due to a healed previous disease. But if these women are examined regularly and suddenly a change from negative to positive is found, the test would speak for a new infection.

This program can be fulfilled entirely only if the practical and theoretical methods for the management of this disease are carried out. The first thing would be to arrange centralized services to cooperate with the different hospitals and clinics and prepare good human vaccine. I believe it would not be difficult to get sufficient quantities of vaccine in this way, at least for diagnostic purposes. Such services have been used in Sweden and Czechoslovakia with success and could be introduced in other places as well. In my few visits to New York hospitals and clinics I have seen several buboes of venereal lymphogranuloma which could furnish a large amount of this material. The service would be of another use, for it is not always easy for the practitioner to make and interpret the test. It would be best if experienced physicians would do it at least in a majority of cases. It would be still more desirable if vaccine of animal origin is to be used.

The International Office of Public Hygiene has not definitely stated whether regulatory measures should be taken in venereal lymphogranuloma as in the other venereal diseases. I believe it is still too early for extensive legal procedures.

A comparison with syphilis, the only venereal disease in which prophylactic measures have had really great success, shows that weapons against venereal lymphogranuloma must be improved on in two directions: In the first place, in syphilis there are two diagnostic methods, the serologic reactions in advanced stages and the darkfield examination for spirochetes in the early and infectious stages. In venereal lymphogranuloma an equivalent convenient method for the examination of the early stages and infectiousness is lacking and has to be worked out with the help of present and future experimental observations. Secondly, in syphilis there are drugs which enable one to destroy the infectiousness in the shortest possible time. In venereal lymphogranuloma such treatment is lacking and has to be searched for by interrelating chemical and animal studies.

There are naturally still many other experimental and practical questions that have to be cleared up in venereal lymphogranuloma. It has been my intention merely to mention those which, from the general point of view, are of special importance in the fight against this venereal disease.

Montefiore Hospital, Gun Hill Road, near Jerome Avenue.

PHENOLPHTHALEIN STUDIES

THE THERAPY OF OVERDOSAGE

BERNARD FANTUS, M.D.

AND

J. M. DYNIEWICZ, Ph.C.

CHICAGO

We have shown in a previous paper¹ that the activated charcoal of the U. S. P. XI has a definite adsorbent action for phenolphthalein, while the non-activated charcoal, such as would have been official according to the specifications of the U. S. P. X, is almost devoid of this effect. We have also shown that activated charcoal given in five times the dose is capable of antagonizing the cathartic action of phenolphthalein in the cat. In the human being we found that a considerably larger excess of charcoal is required but that when such an excess is given the cathartic effect is inhibited.

As there is no well defined plan of treatment available in the literature suitable for the treatment of an

Typical cumulative elimination curves of phenolphthalein in the urine after control dose (phtn.) and control dose followed by agents as indicated.

overdose of phenolphthalein it seemed worth while to test the practical value of charcoal for this purpose by means of an experimental study. Having found it impossible to kill animals—daphnia, worms, mice, cats, dogs, pigs, monkeys—with phenolphthalein administered in any dose, we were forced to study this question on human beings. We therefore administered a fairly large dose of phenolphthalein to volunteers and checked results by noting the degree of cathartic effect as well as the influence on the elimination of phenolphthalein in the urine.

It also seemed plausible that, when an overdose of phenolphthalein is taken, the administration of a rapidly

1. Fantus, Bernard, and Dyniewicz, J. M.: Phenolphthalein Studies: Phenolphthalein and Activated Charcoal, *Am. J. Dig. Dis. & Nutrition* 2: 337-341 (April) 1936.

acting cathartic such as castor oil or magnesium sulfate should sweep out this relatively insoluble and slowly acting cathartic by its greater rapidity of action and thus prevent the excessive purgative effect from an overdose of phenolphthalein.

We therefore projected the following test in which ten volunteers collaborated, each of whom took the following doses at intervals of a week:

Dose 1: 0.30 Gm. of phenolphthalein.

Dose 2: Dose 1 followed in fifteen minutes by 15 Gm. of magnesium sulfate.

Dose 3: Dose 1 followed in fifteen minutes by 15 cc. of castor oil.

Dose 4: Dose 1 followed in fifteen minutes by 7.5 Gm. of activated charcoal. In cases 1, 2 and 3, 15 Gm. of charcoal was given.

Dose 5: Dose 1 followed in fifteen minutes by 7.5 Gm. (15 Gm. in cases 1, 2 and 3) of activated charcoal and followed fifteen minutes later by 15 cc. of castor oil.

Dose 6: Same as dose 1.

The urine was carefully collected throughout the period of time required for the disappearance of the elimination of phenolphthalein in the urine, and the efficiency of the evacuant or adsorbent was estimated by the degree to which the urinary elimination of phenolphthalein was diminished. This, we believe, is a fairly reliable index to absorption as shown by our studies on the urinary elimination of phenolphthalein.²

RESULTS AS TO URINARY ELIMINATION

Table 1 shows that, while there is considerable variation in total percentage of phenolphthalein eliminated in the urine in relation to that ingested (average 3.3 per cent), there is a consistent and marked diminution in the elimination following the administration of activated charcoal, the elimination figure averaging 1.4 per cent, i.e., less than half of the percentage eliminated in the controls. The same average (1.4 per cent) was secured by treatment with charcoal followed by castor oil. Then comes the castor oil figure, which averages 1.75 per cent, and magnesium sulfate winds up with an average elimination percentage of 2.54.

TABLE 1.—Percentage of Phenolphthalein Eliminated in Urine After Evacuants and Charcoal

Case	Phenolphthalein	+ Magnesium Sulfate	+ Castor Oil	+ Charcoal	+ Castor Oil and Charcoal
1	9.03	5.98	4.22	2.39	3.65
2	3.17	3.59	2.28	1.67	1.90
3	1.78	1.65	0.896	0.848	1.18
4	3.31	3.25	1.95	2.35	1.67
5	2.47	2.59	1.97	1.28	1.76
6	2.02	0.96	0.71	1.29	0.36
7	2.92	1.29	0.726	0.896	0.95
8	1.81	1.85	0.69	0.846	0.82
9	2.99	1.76	1.44	0.70	0.68
10	4.10	2.30	2.64	1.71	1.04
Average	3.28	2.54	1.75	1.598	1.404

The results of our experiment with this sequence of doses can perhaps best be visualized by means of the accompanying chart, which represents a typical instance (case 1) of the cumulative elimination percentage of phenolphthalein in the urine in relation to the amount ingested. Even though the curves representing the urinary elimination of phenolphthalein in the various other cases differ in appearance, they—on the whole—tell the same story. It will be seen that the control elimination curve, after the taking of 0.3 Gm. of phenol-

phthalein, reaches the highest point while the elimination curve when charcoal followed is at the lowest level, and this relation is found in all the three cases in which 15 Gm. of charcoal was taken and likewise in some of the cases in which only 7.5 Gm. was taken. The reason for cutting the dose of charcoal in half in the other cases was the difficulty experienced by some of the volunteers in swallowing the entire dose when taken

TABLE 2.—Cathartic Effect of 0.3 Gm. of Phenolphthalein Compared with Succeeding Administration of Magnesium Sulfate, Castor Oil, Charcoal, and Charcoal and Castor Oil

Case	Phenolphthalein	+ Magnesium Sulfate	+ Castor Oil	+ Charcoal	+ Castor Oil and Charcoal
1	+	+++	++	S	+
2	+	+++	++	0	+
3	+	+++	+++	00	++++
4	0	++	+++	00	++
5	++	+++	++++	S	+
6	+	++	+++	S	+
7	++	+++	+++	+	++
8	+	+++	++++	0	++
9	+	+++	+++	0	+
10	+	+++	++++	0	+++

The degree of cathartic effect is indicated by signs: + for definite purgative effect; ++, as well as +++, for more and more severe purgation; S for slight laxative effect; 0 for no effect, and 00 for resulting constipation.

dry (!) or in water. It is very clear from all our observations that the administration of charcoal in about fifty and even in twenty-five times the dose of phenolphthalein greatly lessens the elimination and presumably the absorption of phenolphthalein.

Of the cathartics, castor oil cuts down the height of the elimination curve more than magnesium sulfate, which suggests that castor oil is the better evacuant to be used in case of phenolphthalein overdose if it should be considered of importance to hurry the phenolphthalein through the bowel. That magnesium sulfate is worthless for the purpose is shown in the few instances (cases 2 and 5) in which it actually increased the urinary elimination, as compared with the control, while in some others (cases 4 and 8) this elimination was practically the same in the control and after the use of magnesium sulfate.

The combination of castor oil administered fifteen minutes after the dose of charcoal does not show up to advantage so far as the elimination is concerned when an adequate excess (fifty times) of charcoal is given. In some of the other cases in which only twenty-five times the amount of charcoal was used, the combination with castor oil reduced the elimination below the level produced by either of them alone.

INFLUENCE ON THE CATHARTIC ACTION

There can be no doubt, as shown by table 2, that activated charcoal, given in liberal quantity (at least twenty-five to fifty times), greatly cuts down the purgative effect. While castor oil shows itself the better evacuant for the purpose of sweeping phenolphthalein out of the bowel than magnesium sulfate, the purgation experienced by the persons using either of these evacuants was more distressing than when the phenolphthalein was given alone. This observation, of course, applies merely to the medicinal doses that were used in this experiment; it is entirely possible that, when a large overdose is taken, the use of castor oil might at least cut short the diarrheal period.

Magnesium sulfate, although it should theoretically be better, since it is the more rapidly acting evacuant,

2. Fantus, Bernard, and Dyniewicz, J. M.: Phenolphthalein Studies: Urinary Elimination of Phenolphthalein, to be published.

is less efficient as far as diminishing the elimination of phenolphthalein is concerned, and it is not less disagreeable in its purgative action than the castor oil.

CONTRAINDICATED TREATMENT

It is probable that bowel movement restraining therapy employed by some physicians in such cases is ill advised; for we have found that the less the purgative effect resulting from phenolphthalein (charcoal not having been administered), the greater the degree of absorption. It is probable that restraining the evacuation of phenolphthalein might cause it to exert the maximum possible local effect on the intestinal mucosa. Physicians also have employed the stomach tube in cases of overdosage. Pneumonia ensued in one instance (reported by hearsay). While there may be a justification in the passing of the stomach tube when the physician is called in on such a case shortly after the taking of the dose and especially in case of an allergic person, it can certainly do no good when it is used hours later after the phenolphthalein has left the stomach. The same thing may be said of ipecac, which, being an irritant, may possibly even be harmful.

RECOMMENDATION

We therefore recommend that, in case an overdose of phenolphthalein is taken, there be administered at the earliest possible moment at least twenty-five times—or as large a quantity as one can get the patient to take—of activated charcoal diffused through water. It may be more pleasantly administered in a carbonated drink, such as ginger ale or "coca-cola." It may be given in divided doses. An excess of charcoal is harmless.

If the patient has taken a very large quantity of phenolphthalein, it might possibly be advisable to follow this by a tablespoonful of castor oil.

Passing the stomach tube and washing the stomach should not be undertaken in the treatment of phenolphthalein overdosage unless some phenolphthalein is presumably still in the stomach or the patient is allergic. In case the stomach tube is passed, the dose of activated charcoal should be introduced before the tube is removed. One would indeed be justified in passing the stomach tube to administer the charcoal in case the patient refused to swallow it.

CONCLUSIONS

1. Activated charcoal is recommended as an adsorbent to be used after an overdose of phenolphthalein.

2. Castor oil is a better evacuant to sweep an overdose of phenolphthalein out of the bowel than is magnesium sulfate.

3. The combination of activated charcoal followed by castor oil lessens absorption when an insufficient dose of activated charcoal has been given. However, the cathartic effect of castor oil makes the combined castor oil and charcoal treatment more unpleasant than is the administration of an adequate dose of charcoal without the castor oil.

The Earliest Known Oculist.—Nearly five thousand years ago, during the IIIrd Dynasty, there lived in Egypt a physician named Imhotep, whose reputation was such that he became an administrator of the realm, and finally was deified. However, it was not until the advent of the VIth Dynasty that the earliest known oculist of human history became known. His name was Pepi-Ankh or Iri, and his funeral stele was found near the Pyramids of Giza.—MacCallan, A. F.: *National Policy to be Adopted in a Tropical Country for the Prevention of Blindness*, *Brit. J. Ophthalm.* 22:65 (Feb.) 1938.

THE NATURE OF THE BLEEDING IN JAUNDICE

ARMAND J. QUICK, M.D., PH.D.

MILWAUKEE

The cause of hemorrhage in the patient with jaundice remains a clinical enigma. Although the incident of serious bleeding is relatively low, the gravity of the problem lies in the fact that its occurrence cannot be predicted with any degree of certainty either clinically or by means of the common laboratory methods now available. In recent years the subject has been discussed repeatedly, and thorough historical summaries have been presented by Judd, Snell and Hoerner,¹ Carr and Foote,² Moss³ and others. No attempts will therefore be made to give another comprehensive review of this problem. My purpose in this paper is to present experimental observations made in studying the coagulation of blood which furnish significant information on the nature of cholemic bleeding and to offer practical suggestions for the management of the jaundiced patient.

For the proper understanding and evaluation of these new observations, a short and simple review of the essential mechanism of blood coagulation will be helpful. It is fairly generally agreed that four agents are required for the clotting of blood: (1) prothrombin, (2) thromboplastin, (3) calcium and (4) fibrinogen. The first three interact to form an active enzyme (thrombin), which reacts with fibrinogen, changing it to an insoluble gel (fibrin), which constitutes the clot. The process can be expressed as occurring in two steps:

1. Prothrombin + thromboplastin + calcium = thrombin
2. Fibrinogen + thrombin = fibrin

From these equations one can conclude that a deficiency of any one of the three factors required for the formation of thrombin or the absence or marked depletion of fibrinogen will cause a retardation or even a complete inhibition of clotting. Satisfactory quantitative methods for calcium and fibrinogen have long been available, and naturally these two substances have been repeatedly investigated in jaundice. In none of these studies has a significant alteration of either calcium or fibrinogen been established.

In reference to calcium, Ivy and his associates⁴ have stated that "the general weight of experimental evidence seems to uphold the view that, although a functional deficiency of calcium exists, it has no relation to the bleeding tendency." One may even question whether a functional deficiency exists, for many investigators, including Ravdin, Riegel and Morrison,⁵ Snell, Greene and Rowntree,⁶ Halverson, Mohler and Bergeim,⁷

Koechig⁸ and Walters and Bowler⁹ found no appreciable change in serum calcium either in experimental or in surgical jaundice. Gunther and Greenberg¹⁰ could find no clear evidence for the assumption that a deficiency of calcium existed in obstructive jaundice or that the diffusible or nondiffusible calcium was in any manner significantly altered.

Fibrinogen is rarely diminished in jaundice. As a matter of fact, an elevation of blood fibrinogen is a common finding. Linton¹¹ observed high values even in patients who died of hemorrhage. Lewisohn's¹² patients who bled likewise were found to have a normal or elevated plasma fibrinogen. Moss³ made similar observations in his study of experimental jaundice. One must conclude that neither calcium nor fibrinogen is sufficiently decreased to be considered the cause of bleeding.

Until recently no satisfactory methods for determining prothrombin and thromboplastin were available. This lack no doubt accounts for the failure to consider a deficiency of either of these two important factors as the possible cause of hemorrhage in jaundice. I¹³ succeeded in developing a simple procedure for determining prothrombin in blood. A method was devised which is dependent on the observation that the clotting time of oxalated plasma, when mixed with an excess of thromboplastin and an optimum amount of calcium, can be employed as a direct measure of the prothrombin content of the plasma. In other words, by keeping thromboplastin and calcium constant, the rate of coagulation is dependent on the concentration of prothrombin and can therefore serve as a simple and direct means for determining this important clotting factor in blood.

THE QUANTITATIVE DETERMINATION OF PROTHROMBIN

Four and five-tenths cubic centimeters of blood obtained by venipuncture is mixed immediately with 0.5 cc. of sodium oxalate solution and centrifuged.

One-tenth cubic centimeter of plasma is mixed with 0.1 cc. of thromboplastin solution, and 0.1 cc. of calcium chloride is quickly added. The time required for the formation of a clot after the addition of the calcium chloride is accurately recorded. Normal plasma will clot in from twelve to thirteen seconds. With a decrease in prothrombin, the clotting time is delayed. By means of the accompanying chart one can determine the prothrombin content of blood by the clotting time. As an example, if the plasma clots in thirty-one seconds, one can see that the prothrombin is 15 per cent of the normal.

The following solutions are required:

1. Sodium oxalate: Dissolve 1.34 Gm. of anhydrous pure sodium oxalate in 100 cc. of distilled water.
2. Calcium chloride: Dissolve 1.11 Gm. of anhydrous chemically pure calcium chloride in 100 cc. of distilled water.

3. Thromboplastin solution: Mix 0.3 Gm. of dehydrated rabbit brain with 5 cc. of physiologic solution of sodium chloride containing 0.1 cc. of sodium oxalate. Incubate at 45 C. for ten minutes, then centrifuge at a slow speed for three minutes to obtain a milky supernatant liquid free from coarse particles.

The rabbit brain is dehydrated as follows: after the blood vessels have been carefully removed by stripping off the pia, the brain is macerated in a mortar and extracted with acetone. The solvent is poured off and a fresh amount of acetone added. The process is repeated until a granular powder is obtained. The product is dried at 37 C. and placed in a stoppered container and preserved in a refrigerator. It retains its full activity for a week.^{13a} It is advisable to check the activity of the thromboplastin against a normal plasma.

A study of the prothrombin content of the blood by this method yielded interesting and useful results. The prothrombin concentration of human blood was found to be remarkably constant in normal persons. Curiously, however, the prothrombin content of human blood is only about one fifth that found in the blood of the rabbit, dog and cat, a fact which one probably has to consider when making deductions from animal experi-

Determination of prothrombin in human plasma: The relation of the clotting time of recalcified plasma (containing an excess of thromboplastin) to the concentration of prothrombin.

mentation and applying them to human physiology. Significantly, the prothrombin was found quantitatively the same in hemophilic blood as in healthy subjects. While a normal prothrombin was also found in the majority of jaundiced patients, a certain number showed a definite and, in a few instances, a drastic reduction of this clotting agent.¹⁴

Evidence has now been obtained which clearly shows that a close relationship exists between prothrombin deficiency and the severity of the bleeding tendency in jaundice. With the recognition that prothrombin depletion appears to be the cause of hemorrhage in jaundice and perhaps in other conditions, the desirability of more information concerning this substance becomes evident. Unfortunately the physiologic literature devoted to coagulation furnishes little information concerning prothrombin that can be applied clinically.

The most promising approach to the solution of the prothrombin deficiency in jaundice therefore seemed to be in seeking experimental conditions in which a reduc-

13a. In an evacuated tube, deterioration is extremely slow.

14. Quick, A. J.: Stanley-Brown, Margaret, and Bancroft, F. W.: A Study of the Coagulation Defect in Hemophilia and Jaundice, *Am. J. M. Sc.* **190**: 501 (Oct.) 1935.

tion of this clotting factor could be produced. Three relatively simple but successful ways were found to accomplish this; namely, by avitaminosis (vitamin K deficiency), by a toxin (spoiled sweet clover hay) and by injury of the liver.

After briefly summarizing these experiments, I shall discuss their value in helping to solve the problem of bleeding in jaundice.

VITAMIN K DEFICIENCY

Almquist and Stockstad¹⁵ in this country and Dam and Schönheyder¹⁶ in Denmark discovered that a hemorrhagic disease could be produced in chicks by means of a diet deficient in a new food accessory which Dam has named vitamin K, or koagulation vitamin. Using Almquist's diet, which is complete except for an adequate amount of vitamin K, I¹⁷ was able to detect an appreciable diminution of prothrombin in the chick's blood even as early as the fourth day. When the prothrombin dropped below 20 per cent, a definite hemorrhagic tendency was invariably observed. Small amounts of alfalfa, a food particularly rich in the new vitamin, promptly restored the prothrombin to the normal level and cured the hemorrhagic condition.

SWEET CLOVER DISEASE

In sections of the country in which sweet clover is used as fodder, it is well known that if this hay is spoiled during curing it is apt to cause a serious hemorrhagic disease. Heavy losses due to hemorrhage following simple procedures such as dehorning cattle and castrating bull calves have occurred both in this country and in Canada. Roderick¹⁸ is to be credited for much of the pioneer work on this disease. He observed qualitatively a marked reduction of prothrombin, but his work was handicapped by the lack of a quantitative method. Valuable information was obtained in our laboratory¹⁷ by producing the disease in rabbits and then studying its effect on prothrombin. It was observed that the hemorrhagic tendency ran closely parallel to the decrease in prothrombin. Only when the prothrombin fell below 10 per cent did a serious tendency to hemorrhage become evident. It is of clinical interest that a transfusion with citrated blood promptly elevated the prothrombin of the blood and produced a temporary improvement in the hemorrhagic condition. After twenty-four hours, however, the prothrombin had sunk again to the previous low level. The disease is easily treated, since merely stopping the feeding of the spoiled hay and substituting alfalfa meal promptly cures the hemorrhagic condition. This suggests that the toxin of sweet clover hay exerts its depressing action on prothrombin directly rather than by causing severe organic injury to any organ, such as the liver, and thereby impairing its power to synthesize prothrombin.

INJURY TO THE LIVER

The tendency to hemorrhage following severe parenchymal damage of the liver has long been recognized. The cause of this bleeding also appears to be dependent

on a reduction of prothrombin, as the following experiment illustrates: A female dog weighing 7 Kg. was fasted twenty-four hours and then put under a moderately deep chloroform anesthesia for ninety minutes. The prothrombin remained normal for five hours after the anesthesia but in twenty-four hours sank to 30 per cent of normal and in forty-eight hours reached the low level of approximately 5 per cent. A day later the prothrombin increased to 10 per cent and from then on slowly returned to normal. Similar experiments have been reported by Warner, Brinkhous and Smith.¹⁹ It has been found that carbon tetrachloride given orally can also produce a prothrombin deficiency. A study has been undertaken to determine under which conditions the agent is most effective and to find means for restoring the body's ability to synthesize prothrombin after injury to the liver has occurred.

With the information just summarized, one can arrive at a better understanding of the hemorrhagic diathesis observed in jaundice. Irrespective of the cause for the drop of prothrombin, no serious bleeding was observed until the prothrombin of the blood was reduced to markedly low levels; i. e., below 10 per cent of the normal in human and even lower in rabbit's blood. There is obviously a wide margin of safety in the prothrombin factor, and significantly the coagulation time as measured by the usual methods may remain normal until more than 80 per cent of the prothrombin of the blood is lost. From the chart one can see that coagulation time is very little prolonged until the prothrombin drops to 20 per cent and that only below this level does the time of clotting rapidly increase with further reduction of prothrombin.

It is frequently observed that a jaundiced patient before operation shows no tendency to hemorrhage either clinically or by laboratory tests but nevertheless has serious bleeding soon after the operation. Perhaps in many of these cases a decreased prothrombin concentration exists which is not sufficient to bring the patient into the hemorrhagic zone but enough to exhaust the margin of safety. With the trauma of an operation there may be a further decrease in prothrombin sufficient to exceed the margin of safety and thus bring the patient into the hemorrhagic zone. The converse condition fortunately is also true. A patient with a concentration of prothrombin so low that clotting is very defective is strikingly benefited by even a small transfusion. By restoring only a fraction of the prothrombin, the concentration often is sufficiently raised to bring the prothrombin to a level at which normal clotting occurs. In sweet clover disease it was found that a transfusion was of but temporary benefit, for if the feeding of toxic hay was continued the prothrombin rapidly decreased again. Similarly in the bleeding jaundiced patient, transfusions usually are of only temporary effectiveness.

While transfusions are often of inestimable benefit, they ultimately fail unless the destruction of prothrombin is stopped. The first step therefore is finding the cause for the depletion of prothrombin. Clinical data are disappointingly valueless in even furnishing a clue. Icterus itself cannot be the cause of bleeding, for only a small percentage of jaundiced patients bleed or show any hemorrhagic tendency. It is well known that frequently a deeply jaundiced patient shows no abnor-

mal hemorrhagic tendency and has no postoperative bleeding. On the other hand, patients with a biliary fistula having no evidence of jaundice may have severe hemorrhage.

Likewise, on analyzing the blood of patients with various types of jaundice for prothrombin, I obtained normal results in all but a comparatively small number of cases. Rather than blaming jaundice as the cause of bleeding, it seems much more logical to recognize the possibility that often the two may be resultants of one and the same agent. Thus carbon tetrachloride will cause both an intrahepatic type of jaundice and a fall of prothrombin. Furthermore, one must not overlook the possibility that in some instances the icterus and the hemorrhagic tendency may be entirely independent of each other. In studying the blood of jaundiced patients, it was found that the prothrombin was normal in all but a few cases, and clinically it is well known that the majority of patients with obstructive jaundice do not bleed. In those, therefore, who do bleed, a new factor must be present. These confusing observations which cannot be correlated with the help of existing clinical data can be explained much more satisfactorily by the experimental work that has been described.

The discovery that a food accessory, i.e., a fat soluble vitamin, is required by the organism for the synthesis of prothrombin is of special importance. Hemorrhage has been observed in patients with biliary fistula, as well as in animals in which the fistula was experimentally produced.²⁰ Hawkins and Brinkhous²¹ found a marked decrease in prothrombin and concluded that this was the cause of the bleeding. In a communication to *THE JOURNAL*, I²² made the suggestion that the depletion of prothrombin may be due to the absence of bile acids in the intestinal tract, thus causing a faulty absorption of vitamin K. Recently Greaves and Schmidt²³ have demonstrated that the prothrombin deficiency produced in rats by a biliary fistula or by ligation of the bile duct can be relieved by feeding massive doses of vitamin K or by including bile with the diet. They conclude that bile probably acts as a carrying agent for the vitamin across the intestinal tract. It is more than probable that a condition can result in the human being similar to the experimental condition present in the rat. A patient with biliary abnormalities often is on a prolonged low fat diet, which obviously limits his intake of the fat soluble vitamins. If now a condition supervenes which prevents the entrance of bile into the duodenum, the absorption of vitamin K may be almost completely stopped and in a short time the patient may reach the stage at which a deficiency of prothrombin frankly manifests itself. The possibility of vitamin K deficiency as a cause of bleeding in jaundice therefore cannot be ignored and should unquestionably receive first consideration in handling hemorrhage in a patient with a biliary fistula.

The ease with which the prothrombin of the blood can be reduced to a hemorrhagic level experimentally by hepatotoxic substances such as chloroform or carbon tetrachloride makes it highly probable that in a certain

number of cases of jaundice the hemorrhagic tendency is secondary to damage to the liver. In view of these considerations, the following cases²⁴ are both significant and instructive:

CASE 1.—A woman, aged 55, complained of nausea, vomiting and epigastric discomfort. In the course of a few days, jaundice developed. August 13, two weeks after the onset of her illness, she was admitted to Columbia Hospital. At this time she was deeply jaundiced (icteric index 218) and her clinical condition became progressively worse. Physical examination was negative except for the jaundice and moderate epigastric tenderness. Laboratory studies revealed the following: The icteric index remained over 200 until August 24. The blood count was normal. The urine contained a large amount of bile pigments; the stools were nearly acholic. The hippuric acid test of liver function was 51 per cent of normal. The clinical condition did not improve and a week after admission a severe pruritus developed. August 25, definite signs of bleeding were noted. Curiously at this time the jaundice began to diminish slightly. The bleeding tendency, however, rapidly became alarming. The patient bled for nearly two hours from a scratch on her thigh, and the oozing from a prick of the ear lobe for a blood count was stopped with difficulty. Blood appeared in both the urine and the stools, and the patient had several hematemeses. Large ecchymotic spots appeared below the left breast, thigh and other parts of the body. At this time intensive blood studies were begun.

August 31: Blood prothrombin was less than 2.5 per cent of normal, fibrinogen 0.66 per cent, coagulation time (Lee White) from seventeen to eighteen minutes. Transfusion (475 cc. of blood) promptly stopped the hemorrhagic tendency, except that blood was still found in the urine.

September 1: Transfusion (400 cc.).

September 2: Prothrombin 15 per cent, fibrinogen 0.65 per cent, coagulation time seven minutes.

September 4: Prothrombin 7.5 per cent, fibrinogen 0.65 per cent, coagulation time ten minutes; transfusion (300 cc.).

September 7: Prothrombin 10 per cent, coagulation time seven minutes.

September 8: Prothrombin 8 per cent, coagulation time ten minutes.

September 9: Before transfusion, prothrombin 8 per cent and coagulation time eleven minutes; immediately after the transfusion (550 cc.), prothrombin 20 per cent, fibrinogen 0.72 per cent and coagulation time five minutes.

September 13: Prothrombin 20 per cent, coagulation time seven minutes.

September 14: Prothrombin 40 per cent, coagulation time six minutes.

September 17: Prothrombin 60 per cent, fibrinogen 0.65 per cent, coagulation time five minutes.

September 23: Prothrombin 100 per cent, coagulation time four minutes.

October 4: Hippuric acid test of the liver, 77 per cent of normal. Jaundice had nearly completely disappeared at this time.

A month later the liver function as measured by the hippuric acid test had returned to 90 per cent of normal.

During the first week in December, jaundice again appeared but after two weeks began to subside. December 20 the blood prothrombin was determined and found normal. December 21 the patient was operated on. The common duct was found greatly dilated, owing to an obstruction from a fanlike adhesion. The liver appeared grossly normal. A prothrombin determination two days after the operation again gave normal results. The patient made an uneventful recovery and at no time did she have any abnormal bleeding.

While the exact cause for the intense hemorrhagic condition cannot be definitely stated, it seems reasonable to attribute the bleeding to hepatic dysfunction, especially since another function, the synthesis of hippuric acid, also was markedly reduced

and began to improve at the time the patient was again producing prothrombin. The case clearly was not one of vitamin K deficiency, since no beneficial effects were noted after either powdered alfalfa leaf or an extract of alfalfa prepared according to Almquist's method was given.

The patient was given large amounts of dextrose as well as of gelatin. Undoubtedly these substances had a beneficial effect on the function of the liver, but the spontaneous relief of the obstruction was without question the major factor in her recovery. The repeated transfusions were of inestimable value, for they tided her over a critical period by supplying prothrombin, which her liver was failing to produce. It was most fortunate that she was not operated on at the time the prothrombin was low and the hepatic efficiency, as determined by the hippuric acid test, greatly reduced. It should be pointed out that the coagulation time as measured by the Lee White method became normal as soon as the prothrombin was raised to 15 per cent of normal. The limitation of the coagulation time in determining the bleeding tendency is obvious.

CASE 2.—A boy, aged 5 years, has had since May 21, 1937, multiple abscesses of the liver that have perforated both into the pleural cavity and into the abdomen. These have been repeatedly drained surgically. An icteric index of 27 suggested a mild toxic hepatitis. A prothrombin determination made Jan. 4, 1938, showed that it was 60 per cent of normal. Such a reduction is not sufficiently severe to bring about abnormal bleeding, and clinically no signs of hemorrhage have been observed. In this case the decrease in prothrombin is due undoubtedly to an injury to the liver.

CASE 3.—A boy, born Nov. 24, 1936, had jaundice, which was present at birth and continued. An exploration laparotomy was done Jan. 18, 1937. It was found that the gallbladder was small and empty, and no bile was present in the cystic and common duct and no hepatic ducts were seen. A prothrombin determination, made March 12 and repeated March 19, gave normal results. In this type of case one could expect the development of vitamin K deficiency, but the prothrombin remained normal and no signs of a bleeding tendency were ever observed.

A prothrombin determination of the blood in more than fifty other jaundiced patients yielded normal results. This is in accord with the clinical observation that the incidence of bleeding in patients with jaundice is relatively low.

MANAGEMENT OF THE JAUNDICED PATIENT

Irrespective of the cause of jaundice, several helpful suggestions can be made in the treatment of jaundiced patients, particularly with regard to the prevention of hemorrhage. It is of primary importance to know whether impairment of hepatic function has occurred. While no laboratory test is perfect, a simple method such as the synthesis of hippuric acid can furnish valuable information.²⁵ If the synthesis is reduced much below 50 per cent of normal, the patient is apt to be a poor surgical risk.²⁶ Unless an operation is extremely urgent, the patient should be given the benefit of special preoperative treatment with the aim of improving the function of the liver. The use of dextrose is well recognized, and I have advocated the administration of gelatin because of its high content of aminoacetic acid.²⁷ Vitamin therapy is still to some extent empiric. Viosterol has been found beneficial by McNealy, Shapiro and Melnick.²⁸

In the prophylaxis against postoperative bleeding, the concentration of prothrombin should be closely followed both before and after the operation. Undoubtedly the prolonged bleeding time by Ivy's method⁴ and the defective clot test of Boyce and McFetridge²⁹ are dependent on the depletion of prothrombin and can be employed with profit. The direct determination of prothrombin, as I have outlined, offers, however, the advantage of being quantitative and a good prognostic guide in combating hemorrhage.

If a prothrombin deficiency is found, efforts should immediately be made to restore the level of this clotting factor to a point that assures normal clotting. Should the patient's history suggest a possible vitamin K deficiency, the administration of this food factor either in the form of powdered alfalfa leaf or as an extract prepared by the method of Almquist³⁰ is indicated. One should also administer bile, bile acids or desoxycholic acid to assist in the absorption not only of vitamin K but of vitamins A and D as well. If injury to the liver is present, dextrose, gelatin or aminoacetic acid, calcium and viosterol are the chief therapeutic agents available.

If the prothrombin concentration of the blood is below 15 per cent the only prompt and effective treatment is transfusion. The prothrombin content of the blood should serve as the guide to the time and frequency of the transfusions. Whenever the prothrombin falls below the critical level, which can be approximately stated as from 15 to 20 per cent of normal, another transfusion is indicated. It must be emphasized that this treatment is of only temporary benefit; nevertheless, as long as the patient's prothrombin is kept above the bleeding level, the danger of serious hemorrhage is abated and this allows time for trying various therapeutic means and agents for restoring the body's power to produce prothrombin.

CONCLUSION

Prothrombin deficiency is an important cause of defective and prolonged coagulation of the blood. A wide margin of safety, however, allows nearly 80 per cent of the prothrombin in human blood to be lost before serious hemorrhage occurs. In various types of jaundice the prothrombin may drop to an exceedingly low level, and it has been found that the bleeding tendency corresponds to the prothrombin depletion. Experimentally it has been demonstrated that the prothrombin can be reduced by deprivation of vitamin K, by a toxin such as occurs in spoiled sweet clover hay and by an injury to the liver. In all types of prothrombin deficiency, blood transfusion is a prompt therapeutic means of stopping bleeding, since sufficient prothrombin is supplied to assure normal coagulation, but its beneficial action is temporary. The permanent cure depends on restoration of normal hepatic function. A vitamin K deficiency as a cause of hemorrhage has not been demonstrated clinically, but it is probable that it may be a cause of bleeding in man.³¹

Clinical Notes, Suggestions and New Instruments

EMPHYSEMA OF THE CECUM AND ASCENDING COLON

GEORGE STRENGER, M.D., BROOKLYN

Emphysema of the cecum and ascending colon, as the name implies, is an infiltration of the wall of the intestine with gas. It is a rare condition, there being only ninety-five reported cases, while the case to be reported is the only one on the records of our hospital. Other names for this medical rarity are "cystic pneumatosis," pneumatosis cystoides and "gas cysts of bowel." The occurrence of a similar disturbance in the intestine of swine has been known ever since the early eighteenth century, but the first case in the human body was noted by Colquet and Duvernay in 1825.¹

When the cecum is affected the intestine is covered with many minute vesicles, its wall being greatly thickened and crepitant, so that it feels like lung tissue.² However, in the jejunum and ileum the gas cysts are usually larger and may hang from the intestine and mesentery in grapelike clusters.³ These gas spaces or cysts are most numerous under the serosa and mucosa, although they are scattered throughout all the coats of the intestine. Microscopically they are lined with flattened endothelial-like cells and are surrounded by giant cells and lymphocytes. But in one case, described by Nitch and Shattuck,⁴ the wall of the intestine was infiltrated with numerous polymorphonuclear leukocytes. Usually there is some associated condition such as a peptic ulcer, tuberculosis or ulcer of the cecum.

The pathogenesis of this bizarre condition is obscure. Living cells can secrete gas in considerable quantity, as evidenced in the swim bladder of the fish. But vacuolization of the giant cells so frequently found in the affected intestine has never been noted, nor are these cells found in the swim bladder. Actual secretion of gas is therefore improbable. Another possibility is the liberation of gas from the tissue lymphatics, but here again there is no proof to support such a theory. Is it bacterial in origin? Most carefully studied cases showed no bacteria either on microscopic examination or on culture, although a few authors have reported the finding of gas producing bacilli.¹ One of Nitch's cases showed a polymorphonuclear infiltration of the wall of the intestine but no bacteria.

The most plausible theory is the mechanical one,³ postulating that gas is forced into the wall of intestine through an ulceration or fissure in the mucosa. Thus Bubis and Swanbeck¹ found an ulceration at the base of the appendix in their case, discovered after resection of the involved intestine. Of forty-two published cases studied by these authors, thirty-two presented ulcers of the stomach or duodenum. Peristaltic action forced the gas through such mucosal "breaks" into the other layers of the intestine.

Emphysema of the intestine has never been diagnosed preoperatively. Those patients in whom the disease was limited to the cecum and ascending colon had a palpable boggy tumor in the right iliac region, usually diagnosed as intussusception or appendical abscess.

Therapy depends on the conditions found at operation. Certainly if obstruction is present, resection or side-tracking anastomosis should be done. Nitch⁴ performed a resection of the involved intestine in one of his cases, while Twyman² and more recently Hardt⁵ merely incised some of the vesicles and obtained an apparent cure. The case reported here was treated in yet another manner.

REPORT OF CASE

A white man, aged 37, admitted to the surgical ward of the Jewish Hospital Dec. 29, 1935, had for the past week suffered from attacks of periumbilical colicky pain lasting from three to five minutes and recurring every two to three hours. He had not vomited nor had he had bloody or tarry stools. The bowels had been severely constipated for one year but the patient had not lost weight.

He did not appear acutely ill. The temperature was 99 F. and the pulse 80, regular and of good volume. Examination of the heart and lungs revealed no abnormality. Palpation of the abdomen disclosed a soft, moderately tender mass in the right lower quadrant a little below the level of the iliac crest. The urine was normal. The blood contained 11,100 white blood cells per cubic millimeter and a blood smear study gave a differential count of 60 per cent polymorphonuclear leukocytes, 36 per cent lymphocytes, 2 per cent eosinophils and 2 per cent monocytes. The red blood cell count was 4,600,000 with 83 per cent hemoglobin. Blood sedimentation time was 14 mm. in one hour.

A diagnosis of appendical abscess was made and the abdomen was entered through a gridiron incision in the right lower quadrant. The condition was truly startling. The cecum and lower half of the ascending colon were pink, markedly enlarged and completely covered with innumerable small vesicles containing an odorless gas. The involved intestine was crepitant to the touch, giving one the impression of lung tissue. There were many enlarged lymph glands. The appendix was congested but its surface was free of vesicles. The stomach, duodenum and ileum were normal. The following procedure was then carried out: The peritoneum on the outer aspect of the cecum and ascending colon was incised and the affected portion of the intestine was sufficiently mobilized to make exteriorization possible. Great care was taken to avoid injury to the blood supply. A lymph gland was removed for examination. A sling of Penrose rubber tubing was placed under the intestine, which was then drawn out of the wound and the latter closed around the protruding intestine. A petrolatum gauze dressing was applied and the patient was returned to the ward.

Forty-eight hours later the wound was dressed and, much to my surprise, the intestine appeared perfectly normal. Not a trace of the vesicles remained. It was then decided to replace the intestine in the peritoneal cavity, and so the patient was again taken to the operating room. The exteriorized intestine was gently cleaned with green soap and water and the surrounding skin sterilized with iodine and alcohol. The sutures were removed, the wound was opened and the intestine replaced, there being only a few flimsy adhesions to the parietal peritoneum. A Penrose drain was placed down to the region of the cecum. Within two weeks the wound was healed and the patient was up and about. The department of pathology reported evidence of acute and chronic inflammation in the lymph gland removed at operation. A complete gastro-intestinal x-ray study was made, but the only abnormal finding was some irregularity in the cecum suggesting an inflammatory lesion. The patient was discharged twenty-three days after admission symptom free with his wound well healed.

July 3, 1936, the patient was again admitted with a three weeks history of pain in the right lower quadrant and periumbilical pain beginning ten minutes after meals, without nausea, vomiting or abnormal stools. He had gained weight since his previous admission and did not appear ill. The pulse and temperature were normal. Examination of the abdomen showed some tenderness in the region of the umbilicus and right lower quadrant, where a soft mass, probably the cecum, could be felt directly under a well healed scar. A complete and detailed study of the gastro-intestinal tract revealed no abnormality other than the slight irregularity in the haustrations previously reported. He was placed on a bland diet and discharged twenty days after admission, greatly improved.

The patient's third admission occurred November 5. He had been well until twenty-four hours before arrival at the hospital, when he had a sudden attack of severe epigastric pain without nausea or vomiting, followed several hours later by a bloody stool. He did not appear acutely ill. There was a

soft nontender mass in the right lower quadrant, probably cecum, and a palpable spastic sigmoid. Rectal examination was negative. There were 13,300 white blood cells per cubic millimeter, of which 62 per cent were polymorphonuclears, 30 per cent lymphocytes, 6 per cent monocytes and 2 per cent eosinophils. The feces gave a positive benzidine reaction for blood, and this persisted for eleven days.

A complete gastro-intestinal x-ray study again revealed a persistent constriction in the lower portion of the cecum and irregular projections suggesting diverticula in this region. He was discharged December 8, one month after admission and about one year after his first admission.

Dr. Harry Freund, who has been taking care of the patient, informed me in a recent communication that the mass in the right lower quadrant is no longer palpable and that constipation is no longer present but that mild periumbilical and epigastric discomfort occasionally occurs.

CONCLUSION

In the case of emphysema of the intestine here reported careful clinical, laboratory and x-ray study over a year's period leads one to suspect a mechanical factor in the formation of the gas vesicles found at operation, the gas having been forced through an ulceration in the cecal mucosa. Resection of the involved intestine was not performed. The patient is now practically symptom free.

TRANSMISSION OF INCITANTS OF ENTERIC DISEASE BY UNSTERILE EQUIPMENT USED FOR ADMINISTERING FLUID BY RECTUM

RUTH GILBERT, M.D., ALBANY, N. Y.

Few reports of the transmission of incitants of typhoid and other enteric diseases by rectum have appeared in the literature. Hervey¹ in 1929 published an interesting description of an outbreak of typhoid in a hospital in which apparatus for the Harris drip had evidently been the vehicle for the transmission of typhoid bacilli.

Two similar instances have come to the attention of the Division of Laboratories and Research of the New York State Department of Health. A number of years ago in an investigation of three hospital patients with paratyphoid fever, a study was undertaken of the equipment used for the administration of enemas. Catheters, rubber tubing and funnels were selected from among the supply understood to have been cleaned and ready for use. Laboratory examinations demonstrated that the catheters and tubing had not been properly sterilized. Bacteria of the type found as the result of fecal contamination developed on mediums inoculated with material collected from the inside of the tubes. More recently, several cases of bacillary dysentery occurred in a hospital under similar circumstances. An investigation of the rubber catheters used for administering enemas demonstrated the presence of fecal flora in more than half of them. Transmission of *Endamoeba histolytica* in the same manner might also be expected, since in kittens infection with this species readily occurs following inoculation by rectum.

The danger of transmission of incitants of enteric disease and other species of pathogenic bacteria or protozoa by rectum may be greater than when such micro-organisms are swallowed, since the amount of acid normally present in the gastric contents will kill most types of bacteria or protozoa unless spores or encysted forms are present. Hospital personnel should appreciate that washing alone does not afford adequate protection and that all parts of the apparatus employed for the treatment of one patient should be sterilized before it is used on another.

CHRONIC SUBDURAL HEMATOMA WITH ACUTE PSYCHOTIC MANIFESTATIONS OPERATION AND RECOVERY

D. M. OLKON, M.D., CHICAGO

The interest in this case lies in the acute manifestations of psychotic behavior in a proved chronic subdural hematoma with only minimal neurologic signs.

A white man, aged 37, married, of good health and exemplary habits, actively engaged in business and very alert, was on his vacation when suddenly the following acute symptoms developed: He became confused, completely disoriented as to time, place and person, failed to recognize his wife and immediate family, and became violent. He refused food and water for fear it was poisoned, and expressed many hallucinations and delusions; for example, that people were standing over him with guns to kill him. He was fearful of every one near him and became negativistic, anxious, apprehensive and resistive.

In view of all these manifestations and his refusal of food he was taken to a hospital. While there he walked out in his pajamas and had to be brought back with the aid of the police. On his return to the hospital he became greatly disturbed, screaming that he wanted to die. He still refused food and, as a result, became very weak. The physician in attendance believed his condition to be an acute psychosis and advised his return to Chicago for institutional care.

I saw the patient July 31, 1937, four days after the acute onset. The following history was given by his wife, his older sister, two nephews, one a senior medical student, and a niece. During the past year they had noticed a marked change in his personality. Formerly he had been a person of exemplary habits and of a good disposition. He had now become quarrelsome without particular provocation, avoided his former friends and companions, became secretive and fault finding, and had the idea that his superiors in business "were not giving him a square deal." After work he refused to go out of the house and never seemed to have enough sleep. He complained of frequent headaches and a feeling of tightness in his head. His appetite became poor, he became capricious about his food, and he lost considerable weight. He never vomited. Further inquiry brought out that a year before in June, while driving his car in the daytime, he suddenly felt a sensation in his head as if he had been struck with a hammer. He became confused, dizzy, very tired and weak, and felt great pain in the head. He stopped the car, rested for a time and then drove home. When he came into the house he complained of a "pounding headache" and weakness. A physician was called, who thought the patient suffered from sunstroke, prescribed a tonic for his weakness and "bromo-seltzer" for his headache. His general condition improved, but the headaches continued. For these he took bromo-seltzer three or four times a day without improvement. It was also stated that the previous winter on several occasions he had a tendency to stumble and fall. To these occurrences he paid no particular attention.

When I saw him in his home July 31 he was confused, apprehensive and irrational. He did not know his age or where he was, and he did not recognize his family. He refused examination and did not talk spontaneously. He started to undress in the presence of the women and seemed unconcerned about it. He was very pale and his face had a mask-like expression. His lips were covered with sordes and there was a fetid odor from his mouth. In walking he seemed to stagger to the right. When he was taken to the hospital he resisted so strenuously that it took three men to get him into the car. He kept saying "It is too late; there is no use." Examination in the hospital revealed the following: The skin was cold, clammy and pale. His temperature was 98.4 F., pulse 80, respiratory rate 24. The heart and lungs were normal. The blood pressure was 110 systolic, 70 diastolic. The tonsils appeared swollen and the tongue was dry and coated. The abdomen was sunken, soft and without palpable masses. The prostate was small, smooth and soft to the touch. He was now

Patient presented before the Chicago Neurological Society in November 1937.

in a daze and did not respond to questions or to painful stimuli. He lay in bed completely immobile and soon went into a semi-stupor state. He kept on muttering "death, killing, no use, I am dead, take them away" and the like. During the night he became restless and wanted to get out of bed and jump out of the window. The night nurse had to call in help to restrain him. This behavior occurred three nights in succession.

On neurologic examination the pupils were round and equal, about 4 mm. in diameter, and reacted well to light and in accommodation. The eyegrounds appeared normal. These results were confirmed with the use of homatropine by an ophthalmologist. There was no paresis or paralysis of the extra-ocular or facial muscles or any rigidity of the neck. The deep reflexes of the upper and lower extremities were equal, about 2+. The right knee reflex, however, at times appeared a little livelier. There were no Babinski, Oppenheim, Chaddock or Rossolimo signs, no foot clonus and no paralysis in any muscle group. The grasp reflex was absent. Sensation could not be determined, for he did not react to touch or to thermal or painful stimulation. The abdominal and cremasteric reflexes were not obtained on repeated examinations.

Laboratory examinations of the urine and feces on many examinations gave negative results. The blood count was as follows: red blood cells 5,400,000, hemoglobin 85 per cent (Dare), leukocytes 8,700, polymorphonuclears 51 per cent, lymphocytes 46 per cent, monocytes 3 per cent. Five other examinations showed similar counts, except that the red count went down to 4,500,000. The Widal test was negative. Blood sugar was 109 mg. per hundred cubic centimeters of the fasting blood, and urea nitrogen 23.43 mg. The blood Wassermann and Kahn reactions were negative. Spinal fluid on puncture came out in drops and was clear without any apparent increase in pressure. The laboratory report was as follows: 5 cells per cubic millimeter in undiluted fluid; Pandy reaction negative, Ross-Jones reaction negative, sugar 85.42 mg., total protein 0.48 per cent, Kahn and Wassermann reactions negative, colloidal gold curve 1111000000.

The roentgenologist's report was as follows: "The skull tables show no evidence of increased pressure or erosion, nor is there any evidence of a fracture in any of the views. All of the sinuses are clear; the sella turcica is normal."

At the suggestion of Dr. Eric Oldberg the chest was examined with the fluoroscope and x-ray plates were made. The report stated that the chest was negative for neoplasm or any evidence of metastases; the heart and aorta showed nothing unusual.

The patient's condition did not improve under conservative methods of treatment. It is evident from this study that there were no definite organic abnormalities. Yet from the antecedent history, the acute onset, the former constant headaches and the patient's present condition, I was inclined to think that there was an organic brain involvement and advised ventriculography.

Dr. Oldberg was consulted, and on the seventh day of admission the patient was prepared for ventriculography. The skull was trephined. As Dr. Oldberg looked in on the dura mater he turned to me and said "There is no pressure." However, as he nicked the dura for the insertion of the cannula several ounces of dark blood gushed out. The patient went into shock, but when the head was lowered his pulse and respiratory rate improved and the blood stopped flowing. Dr. Oldberg inserted the cannula for about 3 cm. before he could feel brain tissue, indicating the extent of brain compression. When the patient was returned to bed he complained of a headache but soon relapsed into a stuporous condition. He remained in this state for the following three days. From then on his improvement was steady. His sensorium cleared, he knew all his callers, he had no delusions or hallucinations and he became quite affable. On the twenty-first day after admission he was discharged from the hospital fully recovered. I advised a month's rest, and he went back to his work October 1, a perfectly well man, without any sequelae except the continued absence of the cremasteric reflex. He had gained about 30 pounds (13.6 Kg.) and felt well. He did not remember anything of the entire episode.

SUMMARY

There are a few outstanding points which it might be well to restate:

1. The main symptomatology in this case was that of an acute psychosis without dominant neurologic manifestations.
2. The change of personality antedated the acute onset for about a year.
3. In this instance the subdural hematoma was not due to alcoholism, syphilis, cardiovascular renal disease, diabetes, trauma or any known etiologic factor, and it was chronic in character.
4. Proper drainage of the hematoma produced a complete recovery.
5. Careful search of the literature did not reveal any case of chronic subdural hematoma in which the mental features were predominating and the organic manifestations mainly absent. For these reasons this case is reported.

Special Article

**VITAMINS IN RELATION TO THE
PREVENTION AND TREAT-
MENT OF PELLAGRA**

W. H. SEBRELL, M.D.

WASHINGTON, D. C.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

The exact number of vitamins or dietary factors in the so-called water soluble vitamin B complex that are essential to the human organism is still undetermined. There are four postulated factors about which sufficient evidence exists to warrant discussion in connection with the treatment and prevention of pellagra. These are riboflavin, or vitamin B₂(G), the rat antidermatitis factor or vitamin B₆, the filtrate factor or chick pellagra factor, and the pellagra-preventive vitamin or blacktongue-preventive factor. It is not impossible that two of these may be different names for the same substance. The field is being investigated so actively at the present time that it is almost impossible to make any conclusive statement concerning the identity of factors which have not been chemically isolated.

RIBOFLAVIN OR VITAMIN B₂(G)

There is considerable evidence that riboflavin is not the pellagra-preventive vitamin. Rhoads and Miller¹ reported that they were unable to produce blacktongue with a diet devoid of vitamin G and inferred that blacktongue is due to some factor other than vitamin G. Birch, György and Harris² failed to cure blacktongue with 30 micrograms of riboflavin per kilogram of body

weight per day intraperitoneally, and György³ noted that salmon and haddock, which are good sources of the pellagra-preventive vitamin, were practically devoid of riboflavin.

Dann⁴ treated three cases of pellagra with riboflavin without success. Fouts, Lepkovsky, Helmer and Jukes⁵ treated two cases with riboflavin without success and then successfully treated two other cases with a preparation free from riboflavin. Koehn and Elvehjem⁶ failed to prevent blacktongue with a flavin supplement, and Sebrell, Hunt and Onstott⁷ were unable to cure blacktongue with relatively very large doses of a synthetic riboflavin preparation.

Although riboflavin may not be concerned in the etiology of pellagra, the foregoing evidence must not be interpreted as indicating that riboflavin may not be one of the human dietary essentials. The use of riboflavin in the treatment of neurologic lesions in a case of pernicious anemia has been reported by Kisch.⁸ Sebrell⁹ reported in 1933 the experimental production of a condition in dogs which, in view of evidence recently presented by Sebrell, Onstott and Hunt,¹⁰ was due, very probably, to riboflavin deficiency. It is not impossible that riboflavin deficiency may occur in man simultaneously with, or independently of, pellagra.

VITAMIN B₆, OR THE RAT ANTIDERMATITIS FACTOR

The exact status of vitamin B₆ has not yet been finally determined. György¹¹ and Chick, Copping and Edgar¹² have suggested that it may be identical with the Y factor of Chick and Copping.¹³ Jukes¹⁴ still questions the accuracy of the work on vitamin B₆ and states: "The demonstration of two new factors necessary for the rat, in the vitamin B complex, in addition to vitamin B and flavin, has made it difficult to interpret recent work on the vitamin B complex, particularly with regard to vitamin B₆, which is probably a mixture of the two new factors." There is evidence that vitamin B₆ is distinct from the pellagra-preventive vitamin, and it is now recognized that what has been called rat pellagra in all probability bears no relationship to human pellagra, and that the skin lesions in these experimental animals are due to a deficiency either in

riboflavin (vitamin B₂[G]), or vitamin B₆, or both. Birch, György and Harris² found that pellagra and blacktongue producing diets contained vitamin B₆ and that maize was a good source of vitamin B₆. Copping¹ also found that maize contains vitamin B₆. Walker and Wheeler¹⁵ used 285 Gm. of maize daily per patient in producing human pellagra. Dann⁴ reported that white or yellow maize meal contained vitamin B₆ and Birch and György¹⁷ also concluded that vitamin B₆ is not identical with the pellagra-preventive vitamin. Fouts, Lepkovsky, Helmer and Jukes⁵ successfully treated two cases of pellagra with a preparation free of vitamin B₆.

THE FILTRATE FACTOR OR CHICK PELLAGRA FACTOR

At the present time there is not sufficient evidence to decide definitely whether the filtrate factor or chick pellagra factor is distinct from the pellagra-preventive factor. Fouts, Lepkovsky, Helmer and Jukes⁵ successfully treated two cases of pellagra with a concentrate containing the filtrate factor prepared from rice bran. Koehn and Elvehjem⁶ cured blacktongue with a liver extract which they state was found active for chicks. Sebrell, Onstott and Hunt¹⁰ showed that another preparation containing the filtrate factor contained the blacktongue-preventive factor. Jukes¹⁴ has assayed several foods for the filtrate factor and finds striking differences between the pellagra-preventive value of foods and their filtrate factor value. He finds that beef, whole corn meal and wheat germ are of the same order of potency in filtrate factor value, although corn meal is one of the poorest sources of the pellagra-preventive vitamin, while beef and wheat germ are two of the good sources of this vitamin. This strongly suggests that the filtrate factor is distinct from the pellagra-preventive factor, but more evidence is needed before this question can be answered conclusively.

THE PELLAGRA-PREVENTIVE OR BLACKTONGUE-PREVENTIVE FACTOR

The term pellagra-preventive or blacktongue-preventive factor is applied to the substance originally postulated by Goldberger and Tanner¹⁸ as necessary for the prevention of human pellagra. There is no confusion with regard to the substance referred to when its definition is restricted to this meaning. Whether or not any of the other later identified fractions of the vitamin B complex are identical with this one is problematic, as indicated in the preceding discussion. Whether a deficiency in this factor will produce a symptom complex in rats or in any other experimental animals other than dogs remains to be demonstrated, and tests with pellagra or blacktongue are the only sound experimental methods for work on the pellagra-preventive vitamin at the present time. Human experiments served a very useful purpose before a suitable experimental animal was available and yielded information of immense value which could have been obtained in no other way. and their associates¹⁹ conducted a long series of preventive tests on man. These experiments were conducted by adding the foodstuff to be tested to a known pellagra-producing diet and feeding this supplemented diet to a group of subjects. If pellagra occurred in the group, it was concluded that the food added as a supplement contained little or none of the pellagra-preventive factor in the quantity given. If no pellagra occurred in the group during one year's observation, it was concluded that the food contained the pellagra-preventive factor. These experiments were supplemented by tests with blacktongue in dogs until it was demonstrated that the two diseases were analogous.²⁰

The evidence that blacktongue of dogs and human pellagra are analogous conditions produced by a deficiency in the same dietary factor is as follows: (a) Every food or substance that has been tested in the prevention or treatment of both pellagra and blacktongue and found to be of value in one disease has been found to be of value also in the other; (b) every food or substance tested in both diseases that has proved worthless in the prevention or treatment of one has also proved worthless in the prevention or treatment of the other; (c) the symptomatology is similar in that in both diseases there is a severe stomatitis, a diarrhea, a slight degree of secondary anemia and a dermatitis of the scrotum; finally, the gross and microscopic pathologic appearances are similar.

Many experimental conditions in rats have been described as pellagra-like,²¹ but there is no evidence that a deficiency in the pellagra-preventive factor causes a dermatitis in rats. In 1934 Sebrell²² pointed out that what was being called vitamin G and assayed

by growth of rats did not necessarily bear any relationship to the pellagra-preventive value of the material. Since practically all of the vitamin G determinations of foods have been made by rat growth experiments and the results frequently expressed in terms of Sherman-Bourquin units, which is a measure of their riboflavin content, the tables of the vitamin G content of foods in the various textbooks indicate the riboflavin, and not the pellagra-preventive vitamin, content of foods. These tables therefore should not be used for the selection of foods in the treatment of pellagra. The determinations of the pellagra-preventive value of foods by Goldberger and his associates give the only data that can be safely used in the treatment of pellagra. These data are summarized in the accompanying table.

MULTIPLE DEFICIENCIES AND PELLAGRA

It has been suggested that a deficiency in more than one factor is involved in pellagra and that pellagra as it is now recognized actually consists of two or more different conditions.

In 1918 Goldberger, Wheeler and Sydenstricker²³ suggested that two separate dietary factors may be concerned in pellagra. They said: "The diagnosis of pellagra was restricted to cases presenting a definite, bilaterally, symmetrical eruption. It is suggested that, so defined, pellagra includes at least two commonly associated, etiologically distinct, though closely related, syndromes." Goldberger,²⁴ in his experiments with casein, made particular mention of the fact that the patients had symptoms diagnosed as pellagra *sine* pellagra, although they never developed skin lesions. In 1933 Wheeler²⁵ discussed at some length the possibility of there being two different conditions. Wright²⁶ described a condition in Sierra Leone characterized by glossitis and skin lesions, especially at the mucocutaneous junction, associated with or followed by disorders of the nervous system, which was cured by the use of cod liver oil and yeast. Stannus²⁷ holds that such lesions are manifestations of pellagra. Fitzgerald²⁸ described an outbreak of exfoliative glossitis with ulceration at the angles of the mouth, salivation, gastrointestinal symptoms and diarrhea, which occurred in an Assam prison. Adding 1 ounce of yeast daily to the diet was found to be of value in treatment. Moore²⁹ described a syndrome of loss of visual acuity, sore tongue, sore mouth, white patches at the edges of the lips, and scrotal or vulval rash in school children in Nigeria, which he believes due to food. Landor and Pallister³⁰ have studied a condition in the prisons of Singapore and Johore, characterized by glossitis, lesions in the angles

of the lips, an eczematous condition of the scrotum and, in the later stages, nerve symptoms suggestive of subacute combined degeneration of the cord nearly always accompanied by dimness of vision. Patients with the glossitis and eczema of the scrotum were successfully treated with fresh brewers' yeast, autoclaved yeast, autoclaved marmite, or liver. Cod liver oil and orange juice were without value in treatment. These authors note particularly that the typical dermatitis of pellagra was not present. They state that

Stannus³² is of the opinion that these conditions are pellagra. Ruffin and Smith,³³ as a result of their work with liver fractions, think that there is a deficiency in more than one substance in pellagra, and Sydenstricker and Thomas³⁴ have postulated an intrinsic and an extrinsic factor in pellagra.

In view of the uncertainty surrounding both the number of factors in the vitamin B complex and their physiologic action, it appears not unlikely that some of the symptoms hitherto assigned to the pellagra syn-

*Pellagra-Preventive Value of Foods**

Food	Quantity Used, Gm.	Pellagra-Preventive Value	Food	Quantity Used, Gm.	Pellagra-Preventive Value

* Adapted from "Table Showing the Pellagra-Preventive Value of Various Foods, Pub. Health Rep. 49:754 (June 29) 1934.

† 15 cc. per kilogram of body weight.

‡ 30 cc. per kilogram of body weight.

§ Equivalent to 100 Gm. of liver.

This table is intended primarily for use in the treatment and prevention of pellagra, and only those foods are included which have been tested under controlled conditions in either human beings or dogs or both. In the absence of a quantitative method of assaying the pellagra-preventive vitamin, only the most general terms can be used to designate the pellagra-preventive value of a food. In order to make a division into groups which will be of practical value without being unwarrantedly exact, the words "good," "fair," "slight" and "none" have been selected. The quantity used must be kept in mind in each instance, since smaller amounts than those indicated would in all probability have less value.

"Good" signifies that the indicated quantity of food contained enough of the pellagra-preventive factor to prevent the disease. This is the most valuable class of foods in the prevention and treatment of pellagra.

"Fair" signifies that the indicated quantity of food showed appreciable and in some instances considerable pellagra-preventive value, but one or more of the experimental subjects developed the disease, usually after considerable delay. Thus, a food under this heading contains enough of the vitamin to be of value but should not be relied on alone in the treatment and prevention of the disease. The principal value of these foods lies in the variety of items afforded as adjuncts to the good sources of the preventive factor.

"Slight" signifies that the indicated quantity of food, although failing to prevent the disease, caused a slight delay in onset. Practically, this group may be disregarded in the treatment and prevention of pellagra.

"None" signifies that, in the quantity used, the results of the experiments indicate that the food contains either none of the preventive factor or such a small amount that it may be regarded, for practical purposes, as being entirely without value in the treatment and prevention of pellagra.

"there is much resemblance between the disease we have described and pellagra, but we feel that it would be incorrect to use the term pellagra for it and prefer to consider it avitaminosis B₂." Aykroyd and Krishnan³¹ describe a stomatitis in children in South India due to a deficiency of one or more factors in the vitamin B₂ complex. They did not observe any involvement of the central nervous system and nothing suggesting pellagrous dermatitis or diarrhea was present in their cases. The disease is curable by fresh, unheated or autoclaved yeast, liver and skim milk. The suggestion is made that the condition may be a manifestation of flavin deficiency.

31. Aykroyd, W. R., and Krishnan, B. G.: Stomatitis Due to Vitamin B₂ Deficiency, *Indian J. M. Research* 2:4:411 (Oct.) 1936.

drome may be manifestations of deficiencies in factors other than the one responsible for the typical attack with characteristic dermal lesions for which the names "pellagra" and "pellagra-preventive factor" obviously should be retained. However, since the factors of the vitamin B complex, fortunately, are closely associated in many foodstuffs, these questions become of serious import in treatment only when one begins to treat pellagra with purified vitamin fractions. This has been

32. Stannus, H. S.: Pellagra and Pellagra-like Conditions in Warm Climates: III, *Trop. Dis. Bull.* 33:885 (Dec.) 1936.

33. Ruffin, J. M.; Persons, E. R.; Harvey, H. I., and Smith, D. T.: Evidence for the Existence of Two Factors Necessary for the Successful Treatment of Pellagra or Experimental Canine Black Tongue, *J. Clin. Investigation* 16:663 (July) 1937.

34. Sydenstricker, V. P., and Thomas, J. W.: Some Factors in the Etiology of Pellagra, *South. M. J.* 30:14 (Jan.) 1937.

pointed out recently by Sebrell, Onstøtt and Hunt¹⁰ in connection with a purified rice bran fraction which contained enough of the pellagra-preventive vitamin to cure blacktongue, but the experimental animals died as a result of flavin deficiency. As the various substances in the vitamin B complex are isolated and chemically identified, there is little doubt that in time the factor responsible for the skin lesions in pellagra will be identified. With it will come the solution of the question as to whether the varied clinical changes which in the past have been called pellagra are the result of a deficiency in one substance.

* SUNLIGHT AS A FACTOR IN PELLAGRA

It has been recognized since the very earliest studies on pellagra that sunlight has a deleterious effect on pellagrins. Frapolli³⁵ in 1771, Albera³⁶ in 1784, Gherardini³⁷ in 1792 and Calderini³⁸ in 1844, among other early students of the disease, refer to the effect of sunlight in pellagra. Larriba³⁹ in 1881 thought that the intensity of the erythema depends directly on an internal factor and on the action of sunlight. The literature is extensively quoted by Smith and Ruffin,⁴⁰ who, since the demonstration that a deficient diet is the primary cause of pellagra, have reopened the question of the secondary importance of sunlight. These authors, by keeping pellagrins on a deficient diet, have succeeded in causing the dermatitis to reappear in thirteen out of thirty-five patients by exposing them to the sun. Fouts and Zervas⁴¹ report the reappearance of the dermatitis by exposure to sunlight in a case in which the dermatitis was clearing rapidly and another case in which the dermatitis appeared on the hands after a fifteen minute exposure to the sun. Bigland⁴² states that he was unable to produce skin changes by exposure to the sun, although he thinks that the sun's rays play an important part in the production of the pellagrous dermatitis. Spies⁴³ produced the dermatitis of pellagra in four volunteers who were kept out of direct sunlight while receiving a pellagra-producing diet, and in eight cases the dermatitis healed in spite of long, daily exposure to direct sunlight. In ten patients there was no effect from exposure to radiation from a quartz mercury vapor arc lamp. Crutchfield⁴⁴ saw no appreciable effect on treating ten patients with very small amounts of ultraviolet rays and thinks that trauma is a more important factor than sunlight. Niles⁴⁵ states that exposure to the sun or to radiant heat from a stove or furnace will bring out an erythema in a pellagrin. Bass⁴⁶ reports the development of pellagrous dermatitis from exposure to heat from a stove, and Smith and Ruffin⁴⁰ report three cases

in which severe symptoms followed exposure to a red-hot stove in one instance, a brush fire in another, and an electric heater in a third. Bass⁴⁷ notes that exposure to heat, pressure, trauma and irritating chemicals, as well as sunlight, may cause the skin lesions. Masso⁴⁸ has reported a moderate elimination of uroporphyrin and a copious elimination of coproporphyrin in two cases of pellagra. Sydenstricker and Thomas,⁴⁹ on the basis of the reporting of porphyrinuria in cases of pellagra by Bassi⁴⁹ and Ellinger and Dojmi,⁵⁰ suggest that the dermatitis in pellagra is due to photosensitization by hematoporphyrin. It has not been conclusively established that the excretion of abnormal amounts of any of the porphyrins is a constant observation in pellagra.^{50a} Stannus⁵¹ states that "to those who have studied pellagra closely it has become obvious that there is a tendency for the exanthem to occur in any area of the skin open to trauma of any kind, using the word in its widest sense."

It appears, therefore, on the basis of the evidence now available, that the action of sunlight in pellagra is to be regarded as that of an irritant, and pellagrins should be protected from exposure to sunlight and skin irritants of all kinds. It should be recognized that this is a point of relatively minor importance in treatment and that recovery cannot be expected unless the proper dietary corrections are made.

LIVER EXTRACTS, ANTIPERNICIOUS ANEMIA FACTORS AND PELLAGRA

The first report on the probable value of liver extracts in pellagra is that by Goldberger and Sebrell,⁵² who tested Liver Extract-Lilly in blacktongue and found that in the quantity used it had a therapeutic and preventive effect. Rhoads and Miller⁵³ produced a condition in dogs which they described as chronic blacktongue with anemia, which they were able to prevent by feeding 4 Gm. of Liver Extract-Lilly daily. They failed to demonstrate any improvement, however, on treating the condition with large doses of liver extract parenterally, and the daily intramuscular injection of the liver extract from 50 Gm. of whole liver failed to prevent the anemia and glossitis. The first report on the use of liver extracts in pellagra is that of Ramsdell and Magness⁵⁴ in 1933. These workers treated twenty-two cases by the intramuscular injection daily of 2 cc. of Liver Extract-Lilly, at the same time placing the patients on the general hospital diet. They state that the results were spectacular in that the appetite returned in from three to seven days and there was rapid clinical improvement in all cases. Ramsdell⁵⁵ later added three cases to the series. Ruffin and Smith,⁵⁶ however, saw little or no improvement in five

patients kept on a diet deficient in the pellagra-preventive vitamin and given daily doses of 5 cc. of Liver Extract-Lilly intramuscularly. The treatment of four of these patients was changed to 90 cc. of an aqueous extract of liver daily, by mouth, with rapid recovery. They treated ten additional patients with 90 cc. of the aqueous liver extract daily, by mouth, with satisfactory results. These authors attribute the successful results of Ramsdell and Magness to the good diet used by the latter. Spies⁵⁷ put sixteen patients on a diet deficient in the pellagra-preventive factor and gave ten of these 80 cc. of liver extract intravenously, and six from 24 to 30 cc. of liver extract intramuscularly. All the patients quickly responded. The failure of the treatment of Ruffin and Smith possibly may be explained by the smaller doses used by them or by the fact that a different liver preparation was used. Fouts and Zervas⁴¹ treated four cases of pellagra with liver extract by mouth and intravenously, with satisfactory results. Spies⁵⁸ recommends the oral administration of from 75 to 100 Gm. of liver extract daily, or from three to five intravenous doses of 20 cc. each in the treatment of severe cases of pellagra. Ruffin and Smith⁵⁹ report rapid and complete recovery of twenty out of twenty-one cases of pellagra from the use of a daily dose of a liquid liver extract (Valentine) derived from 675 Gm. of liver (90 cc.) for from five to twenty-five days; with Liver Extract-Lilly intramuscularly in doses derived from 15 to 20 Gm. of liver, only two of nine patients recovered; with Lederle's parenteral liver extract in doses derived from 100 Gm. of liver, none of eight recovered, and with Parke, Davis's liver extract intravenously, one of three recovered. These were treated, however, for only one and two days with doses derived from 200, 250 and 500 Gm. of liver. These results do not agree with the experience of Spies,⁵⁸ who thinks that the treatment of severe cases is most successful when large doses of liver extract are used parenterally.

The evidence appears to warrant the therapeutic use of liver extracts, both orally and parenterally, in severe cases of pellagra. It should be borne in mind that liver extracts are prepared and assayed for use in the treatment of pernicious anemia and that their value in pernicious anemia does not necessarily bear any relationship to their value in pellagra. Therefore, large doses are essential. Their principal value would appear to be as an adjunct to yeast and the dietary treatment, and as a means of parenteral administration of the vitamin when severe vomiting or diarrhea makes the retention and utilization of food by mouth difficult or impossible. They should be used in very liberal doses in conjunction with yeast, milk, lean meat, and all the other foods rich in the pellagra-preventive vitamin.

The possibility that the pellagra-preventive vitamin and the extrinsic antipernicious anemia factor may be identical or related substances has attracted some attention. Before riboflavin was differentiated from the other factors in the vitamin B complex, Strauss and Castle⁶⁰ suggested that the two factors were identical, since they found substances containing the antipernicious anemia factor also to contain the rat growth

promoting vitamin G. Strauss and Castle⁶¹ obtained a response in pernicious anemia with an incubated mixture of normal gastric juice and an autolyzed yeast preparation, and Miller and Rhoads,⁶² using a modified blacktongue-producing diet, described a symptom complex in swine characterized by lesions of the buccal mucosa, achlorhydria, and anemia associated with a loss of the anti-pernicious anemia activity of the gastric secretion. Spies⁵⁸ showed that desiccated hog stomach (Ventriculin) has therapeutic value in pellagra, and Spies and Grant⁶³ also suggested that the antianemic factor may be vitamin G or some closely related factor. Later, Spies, Payne and Chinn⁶⁴ treated cases of pernicious anemia with autoclaved yeast incubated with normal human gastric juice and treated pellagrins with the same lot of autoclaved yeast. There was no remission of the pernicious anemia, although the pellagra was cured. Wills⁶⁵ investigated the hematopoietic effect of several preparations containing the B vitamins, and Wills and Naish⁶⁶ found no response in pernicious anemia with an egg white preparation rich in vitamin B₂. Davidson,⁶⁷ from an investigation of autolyzed yeast products (marmite) in sixteen cases of pernicious anemia, concludes that the hematopoietic factor in marmite, liver and liver extract is not vitamin B₂. Salah⁶⁸ found that the achyllic gastric juice from five pellagrins contained the hematopoietic principle as determined by the rat reticulocyte response and concludes that the extrinsic hematopoietic principle is different from the pellagra-preventive factor. Stare and Thompson⁶⁹ were unable to obtain a hematopoietic response in pernicious anemia with purified hepatoflavin. Subbarow, Jacobson and Fiske⁷⁰ have isolated a fraction from liver which they find both reticulocytogenic in the guinea-pig and therapeutically potent in blacktongue, although the variations in the response of pellagrins to various liver extracts reported by Ruffin and Smith⁵⁹ suggest that the two substances are different. The evidence therefore favors the view that the pellagra-preventive factor and the extrinsic anti-pernicious anemia factor are different substances. Further work on the identification of the factors involved in both diseases is necessary before conclusions can be drawn with regard to the entire lack of relationship between the etiologic factors in the two diseases.

YEAST IN PELLAGRA

Yeast was introduced in the treatment of pellagra by Goldberger and Tanner,²⁴ who used 1 Gm. of dried yeast per kilogram of body weight in treating the disease. Their experience led them to believe that a smaller dose was sufficient, particularly when combined with

proper dietary treatment, and Goldberger, Wheeler and Tanner⁷¹ finally recommended a daily dose of between 15 and 30 Gm. Walker and Wheeler¹⁶ cured experimental pellagra with 30 Gm. of dried powdered yeast daily, while the patients remained on the deficient diet, and Wheeler²⁶ prevented pellagra with a daily dose of 60 Gm. of autoclaved, dried bakers' yeast. Spies, Chinn and McLester⁷² recently have used even larger doses in treatment. No evidence of deleterious effects from overdosage with pure dried yeast have been reported and it is essential that very large doses be given if treatment is to be successful. It becomes obvious that the use of moist yeast cakes or compressed yeast tablets is out of the question, since a moderate daily dose of 10 grain tablets would be 100 tablets. Therefore the only practical method of administration is in the form of pure dried powdered yeast, which must be given in terms of tablespoonfuls. Anything less than this represents insufficient treatment and may lead to failure to secure satisfactory results. Yeast may be conveniently administered stirred into milk, tomato juice and table syrup. A bouillon may be made with warm water and salt, it may be sprinkled on cooked cereals, and Spies⁴¹ has given it successfully in eggnogs.

NICOTINIC ACID AND PELLAGRA

Recent developments have indicated that nicotinic acid may prove to be a valuable therapeutic agent in the treatment of pellagra. Elvehjem, Madden, Strong and Woolley⁷³ have reported that nicotinic acid and nicotinic acid amide will cure blacktongue of dogs. Street and Cowgill⁷⁴ noted beneficial effects in two dogs with chronic blacktongue, and Chick, Macrae, Martin and Martin⁷⁵ cured a similar condition in swine with nicotinic acid. Sebrell, Onstott, Fraser and Daft⁷⁶ have confirmed Elvehjem's results and find that 6 mg. of nicotinic acid twice a week will prevent the disease in dogs on a blacktongue-producing diet during an experimental period of six months. Elvehjem, Madden, Strong and Woolley⁷³ suggested clinical trial of their material in human pellagra. This was also suggested editorially in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.⁷⁷ An editorial in the *British Medical Journal*⁷⁸ has suggested the trial of trigonellin, the methylbetaine of nicotinic acid.

Spies, Cooper and Blankenhorn⁷⁹ noted improvement in the mucous membrane lesions in four pellagrins within twelve hours after administering nicotinic acid. Fouts, Helmer, Lepkovsky and Jukes⁸⁰ reported that, following the administration of 500 mg. of nicotinic acid daily to three patients and 1 Gm. daily to one patient with pellagra, improvement was as satisfactory as that obtained by administering liver filtrate, except

for an increase in the time required for complete disappearance of the dermatitis.

Harris⁸¹ found that one-third Gm. of nicotinic acid daily hastened subsidence of erythema in five cases of pellagra. He has mentioned the possibility that nicotinic acid may not be the sole major deficiency in some pellagra-producing diets.

Spies⁸² observed beneficial effects in fifteen cases and has noted that increased porphyrinuria associated with pellagra disappeared. He recommends the daily administration of 500 mg. of nicotinic acid in 100 mg. doses by mouth or 40 to 80 mg. in sterile physiologic solution of sodium chloride in 10 to 20 mg. doses. He also recommends that all patients be given a well balanced diet when nicotinic acid is used as a supplement.

Smith, Ruffin and Smith⁸³ report recovery of one patient after the administration of 60 mg. of nicotinic acid daily for twelve days.

Spies, Cooper and Blankenhorn⁸⁴ treated seventeen cases (apparently including the fifteen cases previously reported by Spies⁸²) with nicotinic acid. They also mentioned personal communications from other workers citing nine other favorable cases. These authors noted rapid improvement in the mucous membrane lesions and in erythematous skin lesions. They found that advanced, moist ulcerated skin lesions did not seem to be especially benefited and conclude that nicotinic acid is a potent therapeutic agent for treating the mucous membrane lesions of pellagra.

It appears, therefore, that nicotinic acid is either the pellagra-preventive vitamin, or a provitamin or that it is only one of two or more substances necessary for the prevention of all the symptoms described as pellagra or that it may be conjugated with other substances in the body into a more complex essential material. The latter possibility is suggested by the fact that Warburg's enzymes, diphosphonucleotide and triphosphonucleotide, each contain a molecule of nicotinic acid.

Smith, Ruffin and Smith⁸³ have suggested mixing nicotinic acid with table salt as a means of preventing pellagra. This suggestion appears to be premature because there is no information available on the effectiveness of nicotinic acid in the prevention of the disease and because so little is known about its physiologic action. It has been shown further that the diets on which pellagra develop are also deficient in other respects. Attempts to prevent the disease by the widespread use of nicotinic acid might allow the symptoms of vitamin B₁ deficiency, protein deficiency, riboflavin deficiency or mineral deficiency to replace pellagra as a nutritional problem in this country.

Sebrell, Onstott and Hunt¹⁰ and Sebrell and Onstott⁸⁵ have found that dogs on a blacktongue-producing diet to which substances containing the blacktongue-preventive factor are added will die unless riboflavin is also present.

Therefore, although it may be desirable at some future time to attempt to prevent pellagra by the use of nicotinic acid mixed with some commonly used

southern article of diet, the safest procedure at present would appear to be to continue vigorously our efforts to prevent the disease by improving the diet, using nicotinic acid as individual circumstances indicate, and leaving the possibility of its uncontrolled administration to a large section of our population until additional information is available.

THE DIET IN THE TREATMENT OF PELLAGRA

In the present chaotic state of our knowledge about the B vitamins, the successful treatment of pellagra is founded on the use of adequate amounts of substances that have been shown experimentally to be most effective in the treatment and prevention of pellagra.

The earliest experiments of Goldberger and Tanner¹⁸ demonstrated the value of the addition of milk, lean meat and legumes to the diet of the pellagrins. The data on the value of a variety of foods in pellagra are condensed in the table for ease of reference. Goldberger and Sebrell⁸⁶ emphasize the point that in mild cases of pellagra careful feeding is all that is needed. Spies⁸⁷ also finds that mild cases can be treated effectively by a well balanced diet of 4,000 calories or more daily, and adequate rest. The severer cases require more energetic treatment. The severer the case the more important it is that the patient shall eat, and since anorexia is a very common symptom it requires careful individual attention in order to make certain that the patient takes and retains the required food. The main reliance should be placed on large quantities of milk, lean meats, liver, and the other foods listed in the table as good sources of the pellagra-preventive vitamin.

The principal features, in brief, of the dietary management of pellagra recommended by Goldberger and Sebrell⁸⁶ in 1933 are as follows: A food intake of 3,000 calories a day should be the aim (in mild cases correction of the diet is all that is needed). Milk should be the principal item of diet; beef juice or meat soups and broths in small quantities at frequent intervals in gradually increasing amounts; solid food, particularly fresh lean meat and liver as soon as the patient's digestive system will permit; pure dried yeast in one-half to 1 ounce (7.5 to 15 Gm.) doses daily in milk, tomato juice or table syrup, and liver extracts in liberal doses in difficult cases. It should be particularly emphasized that "... success in treatment of the individual case will be in almost direct proportion to the attention devoted to the proper feeding of the patient." Spies, Chinn and McLester⁸⁸ used a similar scheme of treatment which differed essentially in an increase in the food intake to about 4,500 calories a day and an increase in the dose of yeast to from 180 to 270 Gm. daily. Forty-seven of fifty hospital patients with severe pellagra were successfully treated. It is probable that the three deaths were the result of complications.

In view of the foregoing, the essential points in the treatment of pellagra are:

1. Inclusion in the diet of at least 1 quart (liter) of milk daily.
2. A diet of from 3,000 to 4,000 calories or more daily containing, in addition to milk, lean meats, liver and other foods rich in the pellagra-preventive vitamin as given in the table.

3. Not less than 30 Gm. and up to 200 Gm. or more daily of pure dried powdered yeast, depending on the severity of the attack.

4. Liver extracts, either orally or parenterally, in very large daily doses in the severe cases.

5. Feedings at frequent intervals and careful, individual nursing, in order to see that the patient actually eats and retains the large amount of food necessary.

6. Symptomatic treatment as indicated.

PREVENTION OF RECURRENCE

Since the disease develops as a direct result of a deficient diet, it is to be expected that it will recur if the patient returns to his former diet, as soon as his supply of the preventive factor is again depleted. Recurrence, therefore, can be prevented only by bringing about a permanent change in the patient's dietary habits. The pellagrins should not be told to stop eating his corn-bread, grits and syrup. These foods are cheap sources of energy, and it is useless and inadvisable to forbid the pellagrins to eat them. He should be advised to add to these foods the pellagra-preventive foods which he has some prospect of obtaining, such as green, leafy vegetables, fresh or canned milk or buttermilk, lean pork instead of fat pork, canned salmon, haddock and corned beef, poultry and rabbits. It is much more likely that he will follow this advice in some measure than that he will give up his established, basic dietary habits. Dietary advice should not be given in general terms. The dietary habits of each patient should be given careful, individual consideration in detail if a practical means of permanent improvement is to be devised. This can be accomplished best with the expert assistance of a nutritionist or well trained dietitian.

PREVENTION

The prevention of endemic pellagra is simple in theory but difficult in practice. If every normal person received enough of the foods containing the pellagra-preventive vitamin there would be no endemic pellagra. This means eating such foods as lean meat, milk, fish and a variety of vegetables containing the pellagra-preventive vitamin. Even if the patient is economically able to obtain these foods, such factors as availability and dietary habits and customs must be taken into consideration. Goldberger and Sydenstricker⁸⁹ and Wheeler and Sebrell⁹⁰ have pointed out the importance of the home production of foods containing the pellagra-preventive vitamin, especially during the late winter and early spring, and the use of dried, powdered yeast as the most important preventive measures in the areas of the United States in which pellagra is endemic. The widespread distribution of powdered yeast, either free or at the cheapest possible price, is the most effective method of immediate control known. However, this is only a palliative measure, which must be repeated each spring in order to keep down the incidence of the disease. DeKleine⁹¹ also believes that home gardening and the distribution of pure, powdered yeast are two of the most important measures to be employed in the prevention of endemic pellagra. Permanent control can be obtained only by bringing about permanent changes in dietary habits.

OF THE FOLLOWING REPORTS. H. A. CARTER, Secretary.

THERM-O-RAY PORTABLE SHORT WAVE GENERATOR NOT ACCEPTABLE

Manufacturer: Therm-O-Ray Corporation, 420 Lexington
Avenue, New York.

The Therm-O-Ray Short Wave Generator is a diathermy unit advertised and sold directly to the public by lay salesmen. The portable unit weighs approximately 24½ pounds. It comes in a carrying case which resembles a small suitcase. When this is opened, the panel shows three instruments. On the right hand side there is a meter control which regulates the volume of the current. There is a millimeter on the left hand side with figures up to 1500 and red marking slightly beyond that point to indicate danger. In the center, below the open grille work through which the light from the tube is seen, there is a clock dial with figures up to thirty minutes. It is set at the beginning of the treatment for a given length of time and then turns off automatically.

The current is supplied by a single tube. The unit is said to be available for use with either alternating or direct current. It is claimed that the unit will not give an electric shock.

An investigator appointed by the Council called at the New York address of the corporation. The firm's name was not listed in the directory in the lobby of the office building nor did it appear on the door of room 1449. Apparently the firm uses the offices of an investment security company for its headquarters. An attendant connected with that office gave the investigator information requested and in addition a copy of the firm's advertising material. The attendant gave the investigator a treatment for the latter's self-diagnosed condition and the demonstrator offered to send a technician to the investigator's home for further demonstration. He stated that the machine could be used by various members of the family for a number of different conditions. No medical supervision was mentioned.

The advertising matter "Therm-O-Ray, Portable Short Wave Generator for Home Use" has been examined by the Council. The tone of this entire pamphlet is unscientific and obviously written to appeal to the layman. It contains such statements as the following: "Stop that Agonizing Pain! . . . Treat by Inner Heat . . . It relieves without regrets . . . white blood cells—the battle fleet of the blood-stream . . . Inner heat . . . thins the blood . . . When these poisons are carried away the trouble vanishes."

Many suggestions are given for home treatment, including the following: "Daily treatment of 20 minutes will keep internal heat in the body until trouble decreases." A coupon appears in the pamphlet carrying this notation to be filled in by the prospective customer, "Have your technician give me a home demonstration on . . . Have your technician phone for an appointment." A number of diseases are listed as the therapeutic indications for this particular unit, including high blood pressure, pneumonia, bronchitis and sinus disorders.

It is noted in the directions that the patient is warned to space the electrode with clothing or bath-towelings "to absorb whatever perspiration there may be since the rubber of the electrode would prevent either its absorption or evaporation." There is no mention of the real necessity for spacing, to prevent burns! Apparently the machine may be rented, purchased for cash or on the instalment plan, and it is said to be guaranteed for one year.

These selling methods are definitely detrimental to rational therapeutics for the following reasons: First, self diagnosis and self treatment postpone, if they do not actually preclude, proper medical attention; second, it is not the function of salesmen to give medical advice. There is the further danger of immediate harm resulting from unsupervised use of electrotherapeutic equipment, such as burns and shocks.

In view of the foregoing report, the Council on Physical Therapy voted not to include the Them-O-Ray Portable Short Wave Generator in its list of accepted devices.

PALM BEACH MERCURY ARC "COLD" ULTRAVIOLET RAY SUN LAMP NOT ACCEPTABLE

Manufacturer: Ultra-Violet Ray Laboratories, Inc., 206 East
Twenty-Third Street, New York.

The Palm Beach Sun Lamp, a mercury arc "cold" ultraviolet radiation source, has been advertised extensively to the general public. This has resulted in the Council's receiving a number of inquiries concerning the effectiveness of the unit as a sun lamp for home use. In keeping with its policy of investigating units which are before the public, the Council has prepared the following report on the Palm Beach Sun Lamp, which was not submitted for consideration by the manufacturer:

This lamp is available with two stands, either a table or a floor model. The latter is adjustable from 51 to 63 inches and the head can be tilted to any desired angle. The lamps are finished in bronze and ivory baked-on enamel with chrome plated trims. Accessories include an 8 foot extension cord, two pairs of goggles and a built-in automatic time switch.

The burner consists of a spirally wound quartz tube of about 8 mm. external diameter and about 90 cm. in length, mounted in the shallow flat-baked, chromium-plated reflector, which is about 25 cm. in diameter and 5 cm. in depth. It is operated on 110 volts, alternating current, 60 cycles, 100 watts. A graduated switch limits the exposures from one to fifteen minutes, cutting off the current automatically.

Radiometric and erythral tests were performed with the unit. When operated on 115 volts, the total intensity of wavelengths shorter than and including 3,132 angstroms, at a distance of 2 feet (61 cm.) from the front edge of the quartz burner, was 43.7 microwatts per square centimeter. A minimum perceptible erythema was produced on the inner forearm on exposure for sixteen minutes. This is in good agreement with the time of exposure calculated on the basis of the radiometric measurements. At a distance of 1 foot the time of exposure for a minimum perceptible erythema would be about one fourth of this value, or four minutes. The manufacturer recommends two minutes, at a distance of 1 foot, as a safe starting exposure.

Over 95 per cent of the total ultraviolet radiation emitted by a so-called "cold" quartz mercury burner is of wavelengths shorter than about 2,900 angstroms, wavelengths not present in sunlight. With the Palm Beach Sun lamp, over 90 per cent of the ultraviolet is concentrated in the resonance emission line at 2,537 angstroms. This emission line is dangerous because it is likely to cause conjunctivitis and may cause cataract if the exposure is too prolonged. Moreover, on first exposure it activates ergosterol, producing vitamin D; but if the exposure is too prolonged it destroys what it creates. Ultraviolet lamps that may be used with safety in the home emit wavelengths between 2,900 and 3,132 angstroms. These rays are very weak in the "cold" quartz type of lamp. Hence, in the opinion of the Council, such a source is misbranded if called a "sun lamp" and is apt to mislead the public. Instead of "sunlamp," such a device might well be called an "ultraviolet lamp" and the advertising matter should emphasize the fact that such a lamp emits rays of wavelengths injurious to the eyes.

One advertising pamphlet, "Palm Beach Sun Lamp For Home Use," apparently written for the attention of laymen, has been referred to the Council. It makes claims concerning the beneficial effect of ultraviolet radiation for "certain forms of anemia," "sinus infections," "respiratory ailments" and "brightening mentality." In addition, the copy points out that over 90 per cent of the emission is in the region of 2,540 angstroms. Photographs show that goggles are worn during treatments but the copy fails to emphasize the fact that these lamps emit rays which are definitely injurious to the eyes, when unprotected.

In the opinion of the Council, the Ultra-Violet Ray Laboratories is practicing methods that are detrimental to rational therapeutics. The distribution of advertising matter containing misleading claims constitutes an appeal to the public which is likely to be harmful, since it enhances a feeling of false security on the part of the layman.

In view of the foregoing report, the Council on Physical Therapy voted that the Palm Beach Mercury Arc Cold Ultraviolet Ray Sun Lamp is not acceptable as a sun lamp for home use without the supervision of an experienced physician.

SATURDAY, MAY 14, 1938

PROPOSED NEW BUILDING FOR THE ARMY MEDICAL LIBRARY AND MUSEUM

A bill, for which the President has already indicated his approval, authorizing the Secretary of War to construct a building to replace the present Army Medical Library and Museum Building at a cost not to exceed \$3,750,000, was introduced April 28. The bill, if enacted, will provide enlarged facilities for the custody and use of the million or more volumes now in the library and for future expansion. This bill proposes the only possible solution for the present situation. The Army Medical Library, frequently referred to as the Surgeon General's Library, is in fact the library of the entire medical profession of the United States. It is identified with the Medical Department of the Army only because Surgeon General Lovell in 1836 conceived the idea of its organization and because through the interest and enterprise of successive surgeon generals it has been brought to its present magnitude and efficiency. It is the largest medical library in the world, containing nearly 500,000 books. If pamphlets, theses and other manuscripts are included, its total number of volumes is above a million. For many years it has been the mecca of American physicians who are seriously engaged in medical research, teaching and authorship.

Thousands who have never visited the library have obtained through its interlibrary loan system the use in their own homes of medical books that otherwise would have been inaccessible. Many more thousands who have never visited the library and possibly never even heard of its interlibrary loan system have been the beneficiaries of its resources, through the publication of books and of periodical literature made possible only because authors and publishers have been able to avail themselves of its facilities. The physicians of the country now have an opportunity of repaying in part at least the debt they owe the library and to secure for themselves and for the physicians who are to follow the benefits of an even greater library in the

future. If they rally promptly to the support of this bill, it should be possible to procure its enactment even in the brief time that will elapse before the present session of Congress adjourns and thus to save a year or more in planning and construction time.

Under the same roof as the Army Medical Library is the Army Medical Museum, established by the Medical Department of the Army in 1863 and now the largest museum of human pathology in the United States. The building in which both are housed, erected about fifty years ago, is a squat red-brick building, on an inconspicuous and somewhat inaccessible site, utterly incongruous when considered in connection with the magnificent public structures erected in the national capital during recent years. The continuous accumulation of books and periodicals, the enlarged demands for service arising out of the broadening fields of the science and art of medicine and the increase in the number of potential patrons that has resulted from the increase in the number of physicians have combined to make administration difficult. There is urgent need too for the better protection from fire and possibly other hazards of the invaluable collections of books, periodicals and pathologic specimens now housed or crowded into this old and outmoded building.

The pending bill leaves details of the construction of the proposed building to the judgment of the Secretary of War. In the selection of the site, however, the advice of the National Capital Park and Planning Commission is to be requested. This arrangement assures the construction of a building adequate to house the existing library and museum, to provide for future expansion and to meet the needs of physicians and other students of the science and art of medicine who desire to avail themselves of its facilities. It assures also the location of the building in proper relation to existing public buildings and others projected by the Planning Commission and at a point affording the greatest possible convenience to the patrons of the library and the museum. All in all, the enactment of the bill should create in Washington a truly great monument for American medicine.

In the Senate, this bill, S. 3919, was introduced by Senator Sheppard of Texas, chairman of the Committee on Military Affairs, and immediately referred to that committee. In the House of Representatives it was introduced as H. R. 10455 by Representative May of Kentucky, chairman of the House Committee on Military Affairs, to which committee it was immediately referred. Before it can become a law, it must be reported by these committees to the Senate and the House, respectively, and must then run the legislative gantlet. As the present session of Congress is now expected to adjourn at least as early as June, it is imperative that every effort be made to make clear to Congress the importance of this measure and the urgency of prompt and favorable action.

UNJUSTIFIED CLAIMS OF OSMOTHERAPY

New methods of administering remedies are frequently introduced and enthusiastically acclaimed without adequate evidence for their usefulness. While intravenous injection of hypertonic salt solutions increases the specific titer of antibodies, this augmentation of circulatory defenses is apparently accompanied by sufficient injury to the tissues to offset its therapeutic value. This conclusion, by Reploh¹ of the Hygienic Institute, Münster, presumably indicates the end of the commercial exploitation of "osmotherapy" in postwar Germany.

The possibility of increasing the bactericidal titer of the circulating blood by intravenous injection of hypertonic salt solutions was suggested as early as 1890. The term "osmotherapy," however, was not coined till 1922, when it was suggested by Stejskal.² At present numerous hypertonic salt solutions are sold in central Europe, the best known being Bertram's mixture of sodium acetate, sulfate, phosphate and chloride, plus a small amount of iodophenol. Extensive trials of this mixture have been made in veterinary medicine, with a few allegedly successful trials in human medicine. Hartwich and Schulze-Büntje,³ for example, have reported curative results in man particularly in infections with gram-positive cocci.

Reploh called attention to the fact that practically no crucial tests of therapeutic claims have been made on experimental animals although the products are widely exploited commercially. He therefore injected the recommended dose of 5 per cent of Bertram's salt mixture intravenously into normal rabbits and observed the changes in complement titer, opsonic index and bactericidal power for a period of three weeks. Following the intravenous injection of a single dose, irregular fluctuations in complement titer took place during the first thirty-six hours. After this there was a gradual and fairly uniform rise in complement content till the seventh day. The complement remained about 50 per cent above normal for at least three weeks. Almost identical curves were obtained in plotting the changes in opsonic index. There was also a distinct increase in bactericidal titer of the blood serum.

In spite of these demonstrable increases in serologic titer, however, the normal level of antimicrobial resistance was not appreciably raised. Rabbits or mice injected with lethal doses of trypanosomes, spirochetes, neurotropic herpes virus, pneumococci or streptococci, for example, showed no statistically decreased mortality on treatment with Bertram's salt mixture. The only suggestion of therapeutic value was drawn from a relatively small group of rabbits and mice injected intravenously with staphylococci. The seven untreated

control rabbits in this group all died after an average length of life of six days. Six of the nine treated rabbits died at about the same time, while three survived the infection. In mice the ten staphylococcus infected controls all died within five to seven days. Six of the seventeen treated mice survived. A skeptical immunologist would regard this as a "borderline" reaction, of little practical value. Control groups of rabbits and mice treated with a variety of quasispecific chemotherapeutic agents (e.g., arsphenamine) showed a much higher percentage of recovery.

"INDIGESTION" AND ADVERTISED
NOSTRUMS

The versatility of the quack is notorious; he commercializes epidemics and makes disease pay dividends through nostrums. In the department of THE JOURNAL devoted to the work of the Bureau of Investigation attention has been called repeatedly to the number of so-called stomach remedies that have been put on the market during the past few years: "Currier's Tablets," "Kolloyd," "Pfunder's Stomach Tablets," "Tums," "Udga," "Willard's Tablets." The cause of this flood has doubtless been the increased incidence of gastric conditions associated with the worry and mental depression of the period of economic stress through which the nation has passed and is passing.

These dangers have recently been reduced to clinical entities by A. B. Rivers of the Division of Medicine of the Mayo Clinic, who sketches¹ the results of a survey relative to the incidence of dyspepsia among a large number of patients presenting themselves for examination. Rivers and his associates report that "about half of the men forty years of age and older, who come to us primarily because of dyspepsia, are found to have peptic ulcer, cholecystic disease or carcinoma of the gastrointestinal or accessory gastrointestinal tract." Of women of the same age group they reported that two out of five "are found to be suffering from gallbladder disease, peptic ulcer or cancer of the stomach, pancreas or intestine." Every sixth man of the group was "found to have carcinoma of the stomach, pancreas or intestine."

Rivers rightly calls attention to the fact that "Almost any evening, during the height of the radio programs, it is possible to hear four or five smooth-tongued announcers advising rapid and inexpensive methods of curing gastrointestinal difficulties. Drugstore shelves are filled with attractively displayed means of curing indigestion. The highways are bordered by signs indicating how the passers-by can quickly return to the happy state wherein they can again enjoy their food. Magazines and newspapers daily carry thera-

peutic advice regarding gastronomic disturbances for the benefit of their dyspeptic readers."

As Dr. Rivers says, there is a serious responsibility falling on the medical profession of "educating laymen concerning the dangers of heeding nonprofessional advice that they cure themselves of dyspeptic unhappiness, particularly if they have reached middle age." This responsibility, *THE JOURNAL* believes, the profession has not only realized but met. In season and out, week after week and year after year for a third of a century, organized medicine has reiterated the dangers of self drugging. But what shall be said of the responsibility of those newspaper and magazine publishers and those radio station owners—men who cannot be charged with lack of intelligence—who for a price are willing to implant in the minds of the sufferers from digestive disorders the belief that the only hope of escaping the operating table is to buy some so-called patent medicine which is advertised for "stomach ailments"?

RECENT RESEARCH ON SPEECH

The mechanism of speech has been studied recently with the aid of much improved mechanical equipment. The vocal organs have been photographed in monochrome and in color, motion pictures have been made of them in action, they have been observed through periscopes, they have been looked at directly, by reflection and stereoscopically, and they have been examined with the stroboscopic device. With one type of instrument, the larynx can be viewed by from thirty to fifty students at one time. Vivid pictures can be obtained of the vocal cords vibrating sometimes with a razor-like edge and at times with a rounded surface. They have been observed to move up and down and in and out, and one at a different rate from the other. In a review, Kerridge¹ points out that the carrying power of a voice does not seem to bear any relation to the type of respiration or to the vital capacity of the speaker's lungs. The volume of air breathed in and out during speech making has more phonetic significance than other respiratory factors. In experiments on students undergoing speech training, the volume of air was not usually increased by practice. There is, however, large individual variation in respiratory habit. It should especially interest teachers of speech and singing that recent extensive investigations apparently give no basis for training in respiratory habit. The demonstration that people with different respiratory habits speak equally well should save teachers unnecessary labor in trying to change an established habit.

Formerly it was taught that the pitch of the voice was raised when the thyroid cartilage moved downward on the cricoid; now, recent experiments by sev-

eral investigators indicate that an exactly opposite change occurs. Cowan,² in studying the speech of some American actors and actresses, found that the average median pitch level was 141 cycles per second for the male voices and 233 cycles for the female voices. The average pitch range used by them in speech was two octaves. The average standard deviation of syllabic power for all speeches was 5.9 decibels. The mean average rate of speech was 157 words per minute, although only a little more than 50 per cent of the time was taken for the actual speaking. The amount of change during an inflection averaged about two tones, and falling inflections occurred more commonly than rising or level intonations.

The quality of the sound produced can be altered by stimulation of the extrinsic laryngeal muscles. In the thyro-arytenoid muscle there are six fasciculi, all of which have fibers of different origin, different insertions and different actions. There is therefore ample arrangement for varying the extent of the vocal cord which is put under tension. This particular muscle is one of the most quickly acting muscles known. The chronaxia is given as one ten-thousandth of a second.

The older idea of schools of singing that air within the chest vibrates strongly during the use of the "chest register" has been discountenanced in scientific circles. Another tenet of schools of voice training which has been slowly disappearing is "the sounding board effect" of the palate and the teeth. Paget³ pointed out that a soprano would need a palate six feet square and teeth of equal length for any sound reflection to be possible. The actual dimensions of these parts are such that the fundamental tone cannot be affected or the direction of the voice influenced by palatal movement. It is not impossible, however, for the hard palate to influence some of the higher harmonics of short wave length. Voelker⁴ calculated that a hard palate of average size might affect the seventy-eighth overtone in the lowest male voice or the tenth overtone in the highest female voice.

In the recent study of speech there has been much equipment brought to bear on the subject—microphones, amplifiers, oscillographs, acoustic filters, sound films and phonograph records. These devices have thrown light on the complicated way in which speech is produced and on the elaborate pattern of the constantly changing vibration in the air which reaches the ear. As yet, however, little has even been surmised of the processes in the brain which initiate the actions of speech or of those essential to the appreciation of reception.

Current Comment

THE PREVENTION OF PARALYSIS IN POLIOMYELITIS

The seasonable outbreaks of infantile paralysis are not far distant. Last week a statement in the correspondence column of *THE JOURNAL* emphasized the necessity for complete rest for patients in the early stages of this disease. Complete rest is so important that it is usually far better to leave the child in bed at home when the disease is first suspected than to move the patient any appreciable distance to a hospital. When these patients are disturbed or moved as little as possible a majority in whom the disease has not progressed beyond the early stages escape paralysis entirely. Should the patient have paralysis, especially of the extremities, the affected part should be immobilized properly at the earliest moment. Early rest of a weakened muscle under these circumstances will help prevent permanent crippling. Infantile paralysis can be suspected when there is fever, headache, irritability, possibly vomiting, perhaps a tremor in the hands, and especially a tender rigid spine, which makes it impossible for the child to touch his chin to his knee. When such manifestations are present, the spinal fluid may be examined to confirm the diagnosis. Thus far there is no specific effective remedy in the acute stages of infantile paralysis nor any generally accepted preventive.

TYPHOID IN MINNEAPOLIS IN 1935

The epidemic of typhoid in Minneapolis beginning in the first half of May 1935 and lasting until the early part of August is the subject of a final report¹ just made available. From May 4 to August 10, 174 cases were recorded in Minneapolis, contrasting with an average of only twenty-six cases a year in Minneapolis for the five year period preceding 1935. The cases in general were mild in character and there were only six deaths. Eleven patients had received typhoid vaccine, but one of these had completed the immunization course only seven days before the first symptoms developed. The tracing of the source of the epidemic was a careful performance. Conservatively estimated there were about 2,000 typhoid carriers among Minneapolis residents. Possibly, then, there may have been more than twenty-one resident carriers along the watershed contributing typhoid pollution to the water. Furthermore, one case of typhoid was recorded seventeen days before the onset of symptoms in the first epidemic case. The former patient was a resident of an institution from which sewage is discharged into the Mississippi River about 118 miles up the river from Minneapolis. Typhoid bacilli were no doubt present in the polluted water at the point of entrance to the Minneapolis water intakes. The other possible sources of infection—contacts, milk, spring and well water,

1. Report of Investigations of the Typhoid Fever Epidemic, Minneapolis, 1935, by the Minnesota Department of Health.

flooded basements, ice supply and swimming places—also were investigated, but all except the Minneapolis city water supply were eliminated after thorough epidemiologic and laboratory investigations. Sanitary engineering review of the water supply system led to the conclusion that there is a considerable number of physical defects in the pumping stations, the purification plants, the distribution system and the plumbing systems, both public and private. These defects constitute potential hazards which, under certain circumstances, may permit contamination to enter the system. They are remediable, however, and recommendations aimed at their correction and improved administration are outlined in the report.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Hospital News.—The Goldsby King Memorial Hospital, Selma, announces the opening of a new addition which provides facilities for twenty patients. A wing of twenty-nine rooms to provide office accommodations for the staff of the Marcus Skinner Clinic has been added.

Personal.—Samuel R. Damon, Ph.D., formerly with Johns Hopkins University School of Medicine, Baltimore, has been placed in charge of the laboratories of the state department of health, succeeding James G. McAlpine, Ph.D., resigned.—Dr. George E. Newton was recently named health officer of Autauga County with headquarters in Prattville; he held a similar position in Lauderdale County, where he has been succeeded by Dr. Julius E. Dunn with headquarters in Florence. Dr. Dunn was formerly health officer of DeKalb County.—Dr. Oma E. Herndon has been appointed chief medical officer at the U. S. Veterans' Administration Facility, Tuscaloosa, succeeding Dr. Herbert Caldwell, who has been transferred to Ithaca, N. Y.—Dr. George M. Harms, Chatom, has been appointed health officer of Washington County, succeeding Dr. Charles M. Cole, resigned.

ARIZONA

Lectures on Obstetrics.—A series of lectures on obstetrics will be given in Prescott May 23-25, Flagstaff May 26-27, and Jerome May 28 under the auspices of the child and maternal welfare division of the state board of health in cooperation with the Arizona State Medical Association. Dr. Morris Edward Davis, associate professor of obstetrics and gynecology, School of Medicine, Division of Biological Sciences, University of Chicago, will be the lecturer. Physicians throughout the state may attend the courses, which are offered without charge. Similar courses were presented in Phoenix and Tucson.

DISTRICT OF COLUMBIA

Mr. Wiprud Appointed Executive Secretary.—Mr. Theodore Wiprud, since 1929 executive secretary of the Medical Society of Milwaukee County, Wis., has been appointed to a similar position with the Medical Society of the District of Columbia. This is the first time the district society has had an executive secretary.

Society News.—At a meeting of the Washington Medical and Surgical Society May 19, Hon. J. Hamilton Lewis, United States senator from Illinois, will discuss "The Federal Attitude Toward the Medical Economic Problem."—The Washington Ophthalmological Society was addressed April 18 by Drs. Derrick T. Vail Jr., Cincinnati, on "Opticohiasmatic Arachnoiditis"; John H. Dunnington, New York, "Tension in Intra-Ocular Neoplasms," and Harry S. Gradle, Chicago, "Practical Application of Contact Glasses: Demonstration and End Results of Fifteen Years."

ILLINOIS

Tuberculosis Meeting.—The Illinois Tuberculosis Association held its annual meeting at the Illinois Hotel, Bloomington, April 18-19. The speakers included:

- Dr. Hugh A. Beam, Moline, The Tuberculosis Problem in State Institutions.
- Dr. Frederick M. F. Meixner, Peoria, Rehabilitation Programs in England.
- Dr. Henry C. Sweany, Chicago, Silicotuberculosis.
- Dr. Robinson Bosworth, East St. Louis, Legal Regulations Governing Sanatorium Boards.
- Dr. Leon C. Ives, Peoria, Activation of Chronic Pulmonary Disease by Industrial Accident.
- Dr. David O. N. Lindberg, Decatur, Importance of Early Diagnosis of Tuberculosis Among Industrial Workers.
- Dr. Roswell T. Pettit, Ottawa, Medicolegal Aspects of Pulmonary Diseases in Industry.

Chicago

Lecture on Tissue Metabolism.—Dr. W. Fleischmann, docent of physiology and assistant professor, Physiologic Institute of Vienna, will lecture at the Cook County Graduate School of Medicine May 18 on "Principles of Tissue Metabolism."

Health Courses in the Public Schools.—Courses to emphasize the importance of health will be added to public school curriculums, the newspapers report. The new courses will in the beginning be added to the program of about fifty of the 349 elementary schools. In the primary grades, regular teachers will provide training in personal cleanliness and give instruction in health habits. In the intermediate grades various causes of disease will be explained to the pupils. In the seventh and eighth grades they will receive instruction from the physical education teacher.

Course in Gastrointestinal Diseases.—The stomach study group at Michael Reese Hospital will conduct a course on gastrointestinal diseases May 23-June 4. The principal subjects considered will be: ulcers, carcinoma of the stomach, diseases of the colon, the gallbladder and liver, and carcinoma of the colon and rectum. Lectures on the roentgenology, gastroscopy, radiotherapy and pathology of the gastrointestinal tract will be presented. The course is open only to graduate physicians and the tuition fee is \$100; the enrolment fee of \$10 will be applied toward the tuition fee. Further information may be obtained from the Medical Librarian, Michael Reese Hospital, Twenty-Ninth Street and Ellis Avenue.

INDIANA

Semiannual District Meeting.—The fifty-ninth semiannual meeting of the Eleventh Indiana Councilor District Medical Association will be held at Logansport May 18. A golf tournament will be held in the morning and in the afternoon the following will speak:

- Dr. Ross C. Ottinger, Indianapolis, Pitfalls in the Diagnosis of Acute Abdominal Conditions.
- Dr. Gerald F. Kempf, Indianapolis, Uses and Abuses of Sulfanilamide.
- Dr. Stephen D. Malouf, Peru, Acute Perforations of the Gastrointestinal Tract.

Rolla N. Harger, Ph.D., professor of biochemistry and toxicology, Indiana University School of Medicine, Indianapolis, will speak at the banquet.

IOWA

Management of Pneumonia.—A film on "Management of the Pneumonias" was a feature of meetings in Council Bluffs, Creston, Davenport, Ottumwa, Centerville, Washington, Burlington, Mason City and Waterloo, February 28-March 5. The film was edited by Dr. Jesse G. M. Bullock, New York, and shown by Dr. Florian E. Schmidt, Chicago. The pneumonia control measures of the state department of health, with particular reference to diagnostic antipneumococcic serum, were discussed. This serum is supplied to more than a hundred hospitals and laboratories of the state.

KANSAS

Society News.—Dr. Carl O. Rice, Minneapolis, discussed "Injection Treatment of Hernia" before the Wyandotte County Medical Society April 19.—The Southeast Kansas Medical Society was addressed in Fredonia March 7; the speakers included Drs. Sherwin E. Mella and James H. Danglade, both of Kansas City, Mo., on syphilis; Dr. Fred P. Helm, Topeka, secretary, state board of health, showed a film entitled "Public Health Aspects of Syphilis."—A symposium on tuberculosis was presented before the Central Kansas Medical Society in Ellsworth March 24 by Drs. Charles F. Taylor, Norton; Frank E. Coffey, Hays, and Samuel H. Snider, Kansas City, Mo.—Dr. James R. Elliott, Kansas City, Mo., discussed

"Treatment of Arthritis" before the Labette County Medical Society in Parsons March 23.—At a meeting of the Miami County Medical Society in Paola March 9 the speakers included Dr. Norman Reider, Topeka, on headaches.—The Shawnee County Medical Society was addressed in Topeka April 4 by Drs. Noble E. Melencamp, Dodge City, on "Acute Perforation of Peptic Ulcer"; Ray A. West, Wichita, "Postpartum Care of the Cervix with Special Reference to Carcinoma Prophylaxis," and John M. Porter, Concordia, "Diagnostic Errors in the Field of Internal Medicine."

KENTUCKY

Annual Course in Pediatrics.—A series of lectures on diseases of children was begun April 27 under the auspices of the pediatric department of the University of Louisville School of Medicine to be given on Wednesdays for ten weeks at the Children's Free Hospital. There will be three lectures each day and one hour's discussion of cases in the hospital. The instructors are Drs. Philip F. Barbour, James W. Bruce, Lee Palmer, William W. Nicholson, James H. Pritchett, Jacob J. Glaboff, Harry S. Andrews, Aaron A. Shapero, Annie S. Veech and Margaret A. Limper. Similar courses have been given for several years under the chairmanship of Dr. Barbour.

LOUISIANA

Medical Reserve Course.—Tulane University of Louisiana School of Medicine, New Orleans, conducted an inactive duty course of instruction for medical reserve officers of the fourth corps area of the U. S. Army and Navy May 9-13. Enrolment was open to all reserve officers of the medical departments of the army and navy and the medical officers of the National Guard. Dr. Hiram W. Kostmayer was in charge of the course.

District Meetings.—The Fourth District Medical Society was addressed in Shreveport March 1 by Drs. Merritt B. Whitten, Dallas, Texas, on "Myocardial Infarction" and Edward N. Cook, Rochester, Minn., "Transurethral Prostatic Resection."—At a meeting of the Seventh District Medical Society in Crowley, March 10, Drs. George R. Herrmann, Galveston, Texas, spoke on "Present Status of Hypertensive Arterial Disease," and Dean H. Echols, New Orleans, "Trigeminal Neuralgia."

MASSACHUSETTS

Warren Triennial Prize Awarded.—Dr. Henry K. U. Beecher, anesthetist at the Massachusetts General Hospital, Boston, won the Warren Triennial Prize of \$500 recently for an essay on "The Physiology of Anesthesia." Twelve essays were submitted in competition from persons in various parts of the United States, England and Germany. The award, established in 1867 by the late Dr. J. Mason Warren in memory of his father, is presented every three years through the executive committee of the Massachusetts General Hospital.

Session on Health Education.—The twelfth annual conference of the New England Health Education Association will be held in Cambridge June 4-5. The speakers will be Mr. Homer N. Calver, director of health exhibits, 1939 New York World's Fair, and secretary and director, committee on American Museum of Hygiene of the American Public Health Association, on "The American Museum of Hygiene and the Health Exhibit of the 1939 New York World's Fair," and Miss Ruth Evans, assistant supervisor of health and physical education, public schools, Springfield, Mass., on "Building a Health Curriculum in Springfield Schools." At luncheon, Mr. Payson Smith, Graduate School of Education, Harvard University, will discuss "Health Phases of Recent Studies and Surveys in Education."

MINNESOTA

The Bell Lecture on Tuberculosis.—Dr. Arnold R. Rich, associate professor of pathology, Johns Hopkins University School of Medicine, delivered the John W. Bell Lecture on tuberculosis before the Hennepin County Medical Society, Minneapolis, April 14. His subject was "The Influence of Age Determined Factors on the Development of Tuberculosis." The lecture was established by the Hennepin County Tuberculosis Society in honor of the late Dr. John W. Bell.

Society News.—The seventh annual joint meeting of the Wabasha and Winona county medical societies was addressed at the Buena Vista Sanatorium, Wabasha, recently by Drs. James M. Hayes, Minneapolis, on "Acute Abdominal Conditions"; Thomas J. Kinsella, Minneapolis, "Diagnosis and Treatment of Primary Carcinoma of the Lung," and George L. Loomis, Winona, "Intractable Nasal Hemorrhage with Report

of a Case Requiring Ligation of the External Carotid Artery."—The Minnesota Pathological Society was addressed April 19 by Drs. Cecil J. Watson on "Idiopathic Porphyria with Cirrhosis of the Liver" and Elexious T. Bell, "Clinical and Pathologic Study of 180 Cases of Subacute and Chronic Glomerulonephritis." Both are from Minneapolis.

Annual Hospital Meeting.—The fifteenth annual convention of the Minnesota Hospital Association and allied organizations will be held at the Nicollet Hotel May 19-21. The speakers will include:

Dr. Malcolm T. MacEachern, Chicago, Organization for the Care of the Sick.

Dr. Bert W. Caldwell, Chicago, The Hospital's Place in the Community.

Dr. Robin C. Buerki, Madison, Wis., The Education of Hospital Administrators.

Other groups meeting at this time include the Minnesota Record Librarians Association, Minnesota Association of Nurse Anesthetists, Minnesota Society of Medical Technologists, Minnesota Dietetic Association, Minnesota district of the American Association of Medical Social Workers, Minnesota Occupational Therapists Association, Minnesota Association of Hospital, Medical and Institution Librarians.

Dr. Litzenberg Becomes Emeritus Professor.—Dr. Jennings C. Litzenberg, professor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, will retire July 1 with the title emeritus, and will be succeeded by Dr. John L. McKelvey, associate professor of obstetrics and gynecology, Peiping Union Medical College, Peiping, China. Dr. Litzenberg graduated at the University of Minnesota Medical School in 1899, joining its faculty in 1901 as instructor in obstetrics. He became head of the department in 1914. He was chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association in 1928 and has been president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hennepin County Medical Society and the Minnesota Academy of Medicine.

MISSISSIPPI

Society News.—A symposium on tuberculosis was presented before the Clarksdale and Six Counties Medical Society in Clarksdale March 23 by Drs. William D. Hickerson, Sanatorium, Harvey F. Garrison, Felix J. Underwood, Jackson, Henry Boswell and James D. Biles Jr., Sanatorium. In the evening following the banquet Drs. John S. Harter and Duane M. Carr discussed "Surgical Treatment of Tuberculosis."—At a meeting of the Tri-County Medical Society in Wesson March 15, Dr. Richard S. Savage, Brookhaven, discussed "Automobile Injuries—Fender and Bumper"; Lew Wallace, Laurel, executive secretary, state pharmacy board, "Cooperation of Druggists and Doctors" and Dr. William C. Chaney, Memphis, "Diseases of the Thyroid Gland."

NEW JERSEY

Society News.—Drs. George A. Poland, Pleasantville, William J. Carrington, Louis Feinstein and Robert A. Kilduffe, Atlantic City, addressed the Cumberland County Medical Society at its bimonthly meeting in Vineland recently on various phases of gynecology.—Dr. Justin Charles Washburn, New York, addressed the Hudson County Medical Society, Jersey City, April 5, on "Differential Diagnosis of Pruritus."—Dr. Alexander Marble, Boston, addressed the Bergen County Medical Society, Hackensack, April 12 on "Newer Methods in the Treatment of Diabetes."—The Tuberculosis Sanatorium Conference of Metropolitan New York held a meeting at Roosevelt Hospital, Metuchen, May 2 with Dr. Arvid Lindau, Lund, Sweden, as the speaker on "The Role of Bovine Tuberculosis in Man."

NEW MEXICO

Society News.—Drs. Henry T. Safford Jr. and Louis W. Breck, El Paso, Texas, addressed the Grant County Medical Society, Silver City, recently, on "Anal Fistula" and "Fractures of the Forearm and Lower Part of the Leg" respectively.

Lectures on Obstetrics at Roswell and Carlsbad.—Dr. Morris Edward Davis, associate professor of obstetrics and gynecology, School of Medicine, Division of Biological Sciences, University of Chicago, will give two courses in obstetrics for practicing physicians, the first at Roswell May 16-18 and the second at Carlsbad May 19-21. The lectures are sponsored by the medical societies of Chaves and Eddy counties and by the division of maternal and child health of the state department of public health.

NEW YORK

Ban on Parrots.—A sanitary code regulation prohibiting importation, breeding or sale of birds of the psittacine or parrot family will go into effect June 1, the state health commissioner recently announced. A similar regulation will go into effect in New York City July 1.

Outbreak of Septic Sore Throat.—An outbreak of septic sore throat affecting fifty-nine persons in Minetto and vicinity, Oswego County, was traced to the use of raw milk from one dealer who supplied 90 per cent of the milk for the village. A milker who gave a history of a recent attack of sore throat and two cows with mastitis were found on a dairy farm that supplied part of this dealer's milk. The outbreak subsided after pasteurization was begun.

Society News.—The Onondaga County Medical Society held a dinner April 30 for physicians and lawyers in honor of George H. Bond, past president of the New York State Bar Association, and Dr. William A. Groat, Syracuse, president-elect of the Medical Society of the State of New York. At the society's meeting May 3 Dr. William F. Snow, New York, spoke on "Modern Treatment of Syphilis and Gonorrhea" and Dr. William A. Brumfield Jr., Albany, on "Clinical Aspects of Syphilis."—At a meeting of the Syracuse Academy of Medicine May 17 the speakers will be Drs. Eugene Davidoff, on "Present Status of Benzedrine Sulfate Therapy"; Robert J. Mearin, "Insulin Therapy in Dementia Praecox" and Philip H. Rakov, "Treatment of Varicose Veins and Varicose Ulcer."

New York City

Eighth Harvey Lecture.—Dr. Harry Goldblatt, professor of experimental pathology, Western Reserve University School of Medicine, Cleveland, will deliver the eighth Harvey Lecture at the New York Academy of Medicine May 19 on "Experimental Hypertension Induced by Renal Ischemia."

Welch Lectures at Mount Sinai.—Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard University Medical School, will deliver the William H. Welch Lectures at Mount Sinai Hospital May 18 and 20 on "Some New Aspects of Homeostasis" and "The Aging of Homeostatic Mechanisms."

Hospital News.—Dr. George Gray Ward has retired as chief surgeon of the Woman's Hospital after twenty years' service. Dr. Albert H. Aldridge has been appointed to succeed him.—Mr. George Blumenthal, for twenty-seven years president of Mount Sinai Hospital, has retired, it was announced at a dinner in honor of Mr. Blumenthal's eightieth birthday April 7. A plaque acknowledging his services to the hospital will be placed in the main foyer of the building.—Broad Street Hospital, founded in 1917 in the financial district, has filed a petition in bankruptcy, the New York Times reported April 9.—Dr. George White Pickering, London, England, gave two lectures at Mount Sinai Hospital April 27 and 29 on "High Blood Pressure in Man" and "Headache."

Personal.—Dr. Henry Hall Forbes was honored at a testimonial dinner on the tenth anniversary of the New York Bronchoscopic Club. A silver loving cup was presented to Dr. Forbes, who was a founder and early president of the club. Speakers at the dinner were Drs. John M. Lore, president of the club; Westley M. Hunt, first secretary; Chevalier Jackson, Philadelphia; Gordon Berry, Worcester, Mass., and Charles J. Imperatori.—The American Jewish Physicians Committee, an organization for the purpose of building and maintaining the medical department of the Hebrew University in Palestine, gave a dinner April 28 at the Hotel Commodore in honor of Mr. Phelps H. Adams, author of "The Truth About Palestine."—Dr. Louise Doddridge Larimore recently received an award of \$50 from the Woman's Hospital, Philadelphia, in recognition of her invention of a special microscope to be used in diagnosis of cancer. The award was from the Hannah W. Richardson Fund, which provides awards for medical inventions by staff physicians who also are graduates of the Woman's Medical College of Pennsylvania. Dr. Larimore is a former member of the hospital staff and graduated from the woman's college in 1915.—Robert R. Williams, chemical director of the Bell Telephone Laboratories, received the Gibbs Medal of the Chicago Section of the American Chemical Society at a meeting in Chicago April 29.—Frederic S. Lee, Ph.D., professor of physiology, Columbia University College of Physicians and Surgeons, will retire at the end of the present academic year. Dr. Lee is 78 years old and has been teaching at Columbia since 1891. He is a past president of the American Physiological Society, the Society for Experimental Biology and the Harvey Society.

NORTH DAKOTA

State Medical Meeting at Bismarck May 16.—The fifty-first annual convention of the North Dakota State Medical Association will be held at the World War Memorial Building, Bismarck, May 16-18, under the presidency of Dr. Edwin L. Goss, Carrington. The guest speakers will be:

Dr. Frederic W. Schlutz, Chicago, *Prevalence of Deficiency Diseases; a clinic on infant feeding.*

Dr. Bernard Fantus, Chicago, *Some Useful Prescriptions.*

Dr. Ernest Sachs, St. Louis, *Head Injuries.*

Dr. William F. Mengert, Iowa City, *Puerperal Sepsis; Analysis of Obstetrical Cases.*

Dr. Raymond W. McNealy, Chicago, *Diagnosis of Acute Abdominal Conditions; Management of Blood Vessel Injuries and Their Sequelae.*

Dr. Albert M. Snell, Rochester, Minn., *Diagnosis and Treatment of Cholelithiasis; Recent Studies on Obstructive Jaundice.*

The North Dakota Academy of Ophthalmology and Otolaryngology will hold a special assembly Tuesday afternoon at which Dr. Sachs will speak on "Ocular, Otolological and Rhinological Symptoms of Brain Tumors" and Dr. Frederick A. Figi, Rochester, Minn., on "Tumors of the Larynx."

OHIO

Society News.—Dr. Louis E. Prickman, Rochester, Minn., addressed the Summit County Medical Society, Akron, April 5, on "Allergy in General Medicine."—Dr. Allen O. Whipple, New York, addressed the Academy of Medicine of Cleveland, April 15, on "Surgery of the Spleen."—At a meeting of the Clark County Medical Society in Springfield March 10 Dr. Nial L. Burrell presented "Review of 100 Cases of Granular Urethritis in Women."—Dr. Florian E. Schmidt, Chicago, addressed the Tuscarawas County Medical Society, New Philadelphia, March 24 on "Diagnosis and Treatment of Pneumonia."—Drs. Malcolm O. Cook, Harry M. Lowell and Flavius E. Ullrey, Hamilton, discussed "Cholelithiasis and Cholecystitis" at a meeting of the Butler County Medical Society, Hamilton, March 10.—Dr. Delmas K. Kitchen, Detroit, addressed the Ashtabula County Medical Society, Ashtabula, March 8 on "Advances in Endocrine Research and Therapy."—Dr. Robert C. Kirk, Columbus, addressed the Pickaway County Medical Society, Circleville, March 11, on serum treatment of pneumonia.

PENNSYLVANIA

Graduate Assembly.—The Harrisburg Academy of Medicine presented its fifth annual graduate assembly May 4 with the following speakers:

Dr. Charles Bagley Jr., Baltimore, *Emergency Treatment of Injuries to the Skull and Vertebral Column.*

Dr. Samuel M. Peck, New York, *Purpura and Hemorrhagic Conditions: The Value of Snake Venom in Treatment.*

Dr. B. B. Vincent Lyon, Philadelphia, *Diagnosis and Management of Peptic Ulcer.*

Dr. Stanley R. Woodruff, Jersey City, N. J., *Treatment of Urinary Infections.*

Dr. Frank J. Heck, Rochester, Minn., *Treatment of the Anemias.*

Dr. Henry C. Marble, Boston, *Traumatic Surgery: Treatment of Injuries to Hand and Forearm.*

Philadelphia

Gerhard Medal Awarded.—Dr. Warren H. Lewis and Margaret Reed Lewis, A.B., Baltimore, received the William Wood Gerhard gold medal of the Pathological Society of Philadelphia at a meeting April 14. Dr. and Mrs. Lewis delivered the annual conversational lectures of the society on "Cultural and Cytological Characteristics of Normal and Malignant Cells."

Society to Aid Persons with Diabetes.—A group of Philadelphia women has formed the Philadelphia Diabetic Society. A four point program has been adopted. The society will make *insulin* available within the means of all who require it; it will help unfortunate persons to raise funds for artificial limbs, crutches and appliances and will help provide camps for diabetic children. It will help diabetic persons in good condition to find employment and finally will seek to educate both the victims of the disease and the public how to recognize early symptoms and the importance of adequate early medical care. A board of physicians to advise the society has been organized and is as follows: Drs. John W. Bransfield, George M. Dorrance, Lewis K. Ferguson, Sigmund S. Greenbaum, Chevalier L. Jackson, Baldwin L. Keyes, Wilmer Krusen, Louis B. La Place, James L. McCabe, Patrick A. McCarthy, Hubley R. Owen, Anthony Sindoni Jr., Edmund B. Spaeth, Samuel Dale Spotts, William G. Turnbull, George Harlan Wells and Carroll S. Wright. Mrs. C. Fred Rau is president of the executive board of the society.

RHODE ISLAND

Personal.—Dr. Jay Perkins, Providence, has retired as president of the Providence Tuberculosis League and was elected president emeritus. He has been especially interested in tuberculosis work since 1894.

Society News.—Dr. Howard R. Ives Jr., Providence, and J. Howard Brown, Ph.D., Baltimore, addressed the Providence Medical Association March 7 on "Bacteriology of Clean Abdominal Wounds" and "Significance of Double Zone Beta-Hemolytic Streptococci for the Cow and for Man" respectively.

SOUTH CAROLINA

Society News.—At a meeting of the Chester County Medical Society, Chester, April 1, the speakers were Drs. John M. Settle, Great Falls, William J. Henry and John N. Gaston Jr., Chester, all of whom discussed acute arthritis.—Dr. Robert E. Seibels, Columbia, addressed the Medical Society of South Carolina, Charleston, recently on "The Toxemias of Pregnancy."—Dr. Fred W. Rankin, Lexington, Ky., addressed the Columbia Medical Society April 11 on "Modern Management of Malignancy of the Colon and Rectum" and Dr. Allen Izard Josey, Columbia, on "Sickle Cell Anemia." Dr. John H. Musser, New Orleans, addressed the society March 14 on "The Doctor's Disease—Coronary Occlusion" and Dr. James R. Allison, Columbia, on "Granulomas of the Skin."

SOUTH DAKOTA

Society News.—Dr. Edward B. Tophy, Rochester, Minn., discussed anesthesia before the Third District Medical Society at Brookings recently.—The Aberdeen District Medical Society was recently addressed, among others, by Dr. Geoffrey I. W. Cottam, Sioux Falls, on common diseases of the chest.

New Indian Sanatorium at Rapid City.—The Sioux Sanatorium, a \$272,000 government institution for the Sioux Indians, was recently completed at Rapid City. The site, chosen in 1935 by a special board of commissioned officers of the U. S. Public Health Service, was that of a former Indian school. The new building is three stories high, with 150 rooms and space for 114 beds. The nurses' home was remodeled from the old boys' dormitory. Dr. Arthur Joseph Wheeler, superintendent of the Albuquerque Indian Sanatorium, Albuquerque, N. M., has been appointed superintendent.

VIRGINIA

Personal.—Dr. John B. H. Bonner, formerly of Stony Creek, health officer of Sussex County, has been transferred to Prince George County with headquarters at Hopewell. Dr. Francis J. Clements, formerly of Palmyra, has been appointed to succeed Dr. Bonner.

Society News.—Dr. James W. Tankard, Pennington Gap, addressed the Lee County Medical Society in Pennington Gap, recently, on Meckel's diverticulum.—Dr. James Edwin Wood Jr., Charlottesville, addressed the Lynchburg Academy of Medicine March 8 on "Body Weight and Hypertension."—At a meeting of the Richmond Academy of Medicine March 8 the speakers were Drs. Walter L. Nalls, on "Chronic Cystic Disease of the Lungs"; Charles M. Nelson, "The Cause of Chills Following Intravenous Therapy" and Joseph Bear, "Human Sterility."—Drs. Thomas N. Spessard and Roy M. Hoover, among others, addressed the Roanoke Academy of Medicine in March on "Hysteria" and "Colles' Fracture" respectively.—Among speakers at a quarterly meeting of the Southside Virginia Medical Association in Franklin March 15 were Drs. Thomas F. Wheeldon on "A Threefold Method of Fixation of Fractures"; William B. Porter, "Hyperthyroidism in the Negro," and Harry Hudnall Ware Jr., "Treatment of Eclampsia." All are of Richmond.—Dr. Marion B. Sulzberger, New York, addressed the Norfolk County Medical Society March 21 on "Management of Common Dermatoses by the General Practitioners."

WASHINGTON

Surgical Meeting.—The annual meeting of the Spokane Surgical Society was held April 30 at the Davenport Hotel, with Dr. Harry E. Mock, Chicago, as the guest speaker. Dr. Mock spoke in the afternoon on "Appendicitis and Lesions of the Biliary Tract" and at the banquet on "Head Injuries."

PUERTO RICO

Society News.—Dr. Hugh H. Young, Baltimore, addressed the Puerto Rico Medical Association January 28 on prostatic conditions. Dr. Ernest E. Irons, Chicago, addressed the San Juan County Medical Association February 21 on "Drugs and the Protection of the Profession and the Public."

GENERAL

New Head of the Red Cross.—Norman H. Davis, ambassador at large and adviser to the State Department on European Affairs, was appointed by President Roosevelt April 12 as chairman of the American Red Cross to succeed the late Dr. Cary T. Grayson. Mr. Davis will continue his diplomatic career, the President said.

Meeting on Epilepsy.—The American League Against Epilepsy will hold a joint scientific session with the section on convulsive disorders of the American Psychiatric Association June 6 in San Francisco at the Fairmont Hotel. The League will also have a dinner meeting at the Fairmont June 7. Dr. Temple S. Fay, Philadelphia, is president and Dr. Frederic A. Gibbs, Boston, secretary.

Grants Available for Research.—The Committee on Scientific Research of the American Medical Association invites applications for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms and further information, please address the committee at 535 North Dearborn Street, Chicago.

Northwestern Alumni Meeting in San Francisco.—Medical alumni of Northwestern University will hold a reunion at a luncheon Wednesday June 15 during the meeting of the American Medical Association. The luncheon will be at 12 o'clock at the Hotel Whitcomb, 1231 Market Street, with Dr. James G. Carr, Chicago, as the speaker. Drs. Frederick J. Carlson, 371 Thirtieth Street, and Claire Rasor, 1624 Franklin Street, both of Oakland, are in charge of arrangements.

Society News.—Alpha Epsilon Delta, honorary premedical fraternity, held its annual meeting at the University of North Carolina, Chapel Hill, March 24-26. Among other events were addresses by Drs. Addison G. Brenizer, Charlotte, N. C., on "Surgical Anatomy of the Thyroid Gland and Thyroidectomy" and William de B. MacNider, dean of the University of North Carolina School of Medicine, on "The Biologically-Minded Physician." Maurice L. Moore, Ph.D., Drexel Hill, Pa., is grand secretary of the fraternity.—Dr. Oliver H. Perry Pepper, Philadelphia, was chosen president-elect of the American College of Physicians at the annual meeting in New York April 4-8 and Dr. William J. Kerr, San Francisco, was installed as president. The following were elected vice presidents: Drs. James B. Herrick, Chicago; Noble Wiley Jones, Portland, Ore., and Charles T. Stone, Galveston. The 1939 meeting will be held in New Orleans.—The annual meeting of the American Rheumatism Association will be held in San Francisco at the University of California Hospital June 13.

Post-Convention Cruise to Alaska.—The California Medical Association has arranged to charter a steamer for a post-convention cruise to Alaska June 17 to July 1 after the Annual Session of the American Medical Association in San Francisco June 13-17. The party will leave San Francisco Friday June 17 by train, stopping at Portland, Ore., for a sightseeing trip that includes the city, Columbia River and Bonneville Dam. Then it arrives in Seattle early Sunday June 19 and by steamer to Victoria for a tour of that city. The Canadian Pacific steamer *Princess Alice* sails for Alaska Sunday evening. The rate from San Francisco and return to San Francisco is \$240 and up, depending on the type of accommodations. For persons who hold tickets to return on the Canadian Pacific Railroad by way of Lake Louise and Banff, the rate from San Francisco back to Vancouver will be \$181. Those interested should make reservations at once by sending a deposit of \$50 per person. If the necessary number of persons is not secured by May 20 the deposit will be returned at once. Make checks payable to Earle J. Harris, 95 Market Street, San Francisco, who is in charge of the tour. Dr. Junius B. Harris, 450 Sutter Street, San Francisco, is chairman of arrangements.

LATIN AMERICA

National Institute of Health Opened in Peru.—A new National Institute of Hygiene and Public Health in Lima, Peru, was officially opened by the president of the republic February 12, according to a report to the U. S. Department of Commerce. The institute, created by a government decree July 23, 1937, will be under the supervision of the ministry of public health, labor and social welfare. Dr. Telemaco Battistini will be the director. It will have three departments: bacteriology and immunology, entomology and experimental medicine. The department of bacteriology and immunology, which will be directed by Dr. Battistini, will engage in the manufacture of serums, vaccines and glandular extracts, which will be sold to government controlled hospitals, municipalities

and certain other public agencies at cost. The department of entomology, under the direction of Marshall Hertig, Ph.D., formerly of Harvard Medical School, Boston, will for the present work exclusively on Carrion's disease, or "verrugas," which is endemic in certain areas of Peru, notably in Verrugas, about 99 kilometers from Lima. Later it is expected that research will be instituted on malaria, which causes the greatest morbidity of any disease in Peru. The department of experimental medicine, which will be directed by Dr. Alberto Hurtado, professor of medicine in San Marcos University, will cooperate with the department of entomology in its study of Carrion's disease. The new institute is equipped with modern apparatus, including air conditioning. Stables have been provided and the institute now has twenty-four immunized horses.

Government Services

New Station Hospital at Fort Sam Houston

A new seven story station hospital for the Eighth Corps Area, U. S. Army, was opened at Fort Sam Houston, Texas, in February. The building is of modified Spanish design and has a capacity of 418 beds. On the first floor are the executive and administrative offices, the medical library, the staff conference and board rooms, the kitchen and dining rooms; in the wings are the urologic ward, the outpatient service, the eye, ear, nose and throat clinic, the dental clinic and the pharmacy. The officers' and women's wards, the laboratories and the offices of the chiefs of medical and surgical services are on the second floor. The third and fourth floors are mainly surgical, with the air-conditioned operating section in the rear

New U. S. Army Hospital at Fort Sam Houston.

wing of the third; the rear wing of the fourth is occupied by the x-ray department, equipped for long and short wave therapy. General medical cases are cared for on the fifth floor, which has a special air-conditioned ward of ten beds for allergic patients. The sixth floor has wards for eye, ear, nose and throat and for obstetric patients and the seventh is reserved for tuberculosis patients. The pediatric clinic and the physical therapy section are in the basement, which also contains most of the nonprofessional services of the hospital. A sub-basement houses the heating plant and other service machinery.

Dr. McCoy Accepts Post at Louisiana University

Dr. George W. McCoy, medical director, U. S. Public Health Service, Washington, D. C., has been appointed head of the department of preventive medicine at the Louisiana State University School of Medicine, New Orleans, effective in September. He will retain his status as an active member of the public health service and will carry on his epidemiologic studies of leprosy as it prevails in certain of the gulf coast states and elsewhere, if necessary. A native of Cumberland Valley, Pa., Dr. McCoy is 61 years of age and a graduate of the University of Pennsylvania School of Medicine, class of 1898. He was appointed assistant surgeon of the Public Health and Marine Hospital Service in 1905 and in 1913 surgeon in the public health service. He was named medical director July 1, 1930. Dr. McCoy was in charge of the U. S. Plague Laboratory, San Francisco, from 1908 to 1911, director of the U. S. Leprosy Station, 1911-1915, serving during this period also as sanitary adviser to the Hawaiian government. From 1915 to 1937 he was director of the National Institute of Health, formerly known as the Hygienic Institute. He was president of the Washington Academy of Sciences in 1935. He is a member of the Council on Pharmacy and Chemistry of the American Medical Association.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 16, 1938.

Epidemics in Schools

Seven years ago the Medical Research Council appointed a committee to investigate epidemics in boarding schools, and the report has just appeared. The number of children from 10 to 19 years of age concerned in the investigation was 22,166 boys and 7,600 girls. The main object was to study the incidence with a view to better control and to see how far the lessons learned from herds of animals could be applied to man. Nasopharyngeal infection was common; the average number of boys attacked during a term was 17.4 per cent. Influenza, which is included in this group, caused 43 per cent of the loss of school time. The disease did not seem to confer any lasting immunity. Those who had it one year seemed to be more likely to succumb to a subsequent epidemic. Of infectious diseases 90 per cent of all cases among boys occurred in the first two calendar terms. The epidemics of the various infectious diseases differed in their ability to work themselves out before the end of the term. Whereas about half the outbreaks of measles came to a natural conclusion, no epidemics of German measles and only a small proportion of mumps, varicella and scarlet fever outbreaks finished before the holidays began. As about 70 per cent of the boys had measles and varicella before entering school, the difference between these two epidemics has no obvious explanation.

Otitis media, pneumonia and rheumatism showed striking differences of incidence as between the sexes, boys suffering twice as frequently as girls from otitis media, two and one-half times as frequently from pneumonia and eleven times as frequently from acute rheumatism. This difference may be partly due to stricter supervision of such cases in their early and uncertain symptoms among girls. The one serious illness from which girls suffered more severely than boys was appendicitis. Girls reported approximately 50 per cent more cases and about 10 per cent more operations. There was no evidence that removal of the appendix had any effect on subsequent sickness rates.

REMOVAL OF TONSILS

About half of the boys and rather under half of the girls had had their tonsils removed, and a yearly census in the school showed an increase by 6 per cent in the former and 7 per cent in the latter. Though recognizing the value of the operation in carefully selected cases, the committee gravely doubted "whether the majority of the tonsillectomies performed today are the result of true discrimination rather than of routine ritual." Actually the incidence of coughs, colds and sore throats in those with and without their tonsils did not differ.

Protection in Air Raids

The government has issued further instructions to local authorities on protection in air raids. One of the most urgent is the recruitment and training of personnel for the duties of air wardens, first aid parties and decontamination squads. A survey of hospital accommodation is being made in cooperation with health officers. It is held that in the event of an air raid the wisest policy is the dispersion of the population to their own homes, but in the neighborhood of crowded thoroughfares public shelters will be necessary. Evacuation of towns and cities may be adopted. The government will provide equipment for ambulance work, first aid posts and clearing hospitals. The public is urged to increase the natural protection of their own homes by the measures which the government has advised and which can be carried out at little cost. These include the sealing of doors and windows against

poison gas by paste and paper. The same situation applies to business premises where a large amount of accommodation can be made available and where adaptation and strengthening of the use of sandbags will give protection.

Great Britain is more advanced than any country in the world in the provision of gas masks. In an emergency the whole population could be supplied within eight hours and the arrangements even include a protective device for babies which totally encloses the child. If properly put on the respirator will protect eyes, nose, mouth and lungs and by means of the filters supply pure air for breathing in the presence of any gas known to be used in warfare. The masks will not be issued to individuals beforehand, because special storage conditions are necessary. They will be in the custody of every local authority, which will be responsible for obtaining particulars as to numbers and sizes and for their ultimate distribution. They will be kept in "local respirator stores," which in large towns will accommodate as many as 30,000. The local authorities are required to furnish particulars of the number of men, women and children between the ages of 4 and 16 years, between 2 and 4 and under 2 years. On obtaining this information they will make arrangements for the supply of the corresponding sizes to the local stores. As the value of the respirator depends to a large extent on its fit, it will be necessary to ascertain by actual fitting the correct number of each size required. This will require a house to house census by the air wardens. Trials have demonstrated that the maximum number of respirators which can be satisfactorily dealt with by one distributing depot is 4,000, which means that each store will require seven or eight depots. The air wardens employed on the census must have undergone antigas training. They will record on cards particulars for forty dwellings and use separate cards for each street. Periodically, say every three months, they will revisit and note on the cards any changes.

Precautions Against the Pollution of Water Supplies

The recent outbreak of typhoid in Croyden, a populous district on the outskirts of London, affected 310 persons of whom forty-three died. It aroused such an outcry that the government appointed a commission of inquiry, which reported that the outbreak was due to infection of a chalk well with the typhoid bacillus. The inquiry revealed that work had been done on the well just before the outbreak and that while ample lavatory accommodation was provided at the surface for the workmen, there was opportunity for relief in a long dark gallery where water was flowing. Moreover, one of the workmen was found to be a typhoid carrier and the conclusion was that he was the source of the outbreak. Recommendations were made for safeguarding the water supply of Croyden in the future. Regulations have been made which are more stringent than any previously adopted in this country. Persons engaged in work with wells, reservoirs or mains or on work which might bring them into contact with a water supply will be required to give their complete medical history and to undergo a blood test. If positive results are obtained, a detailed examination will be made. No person who has suffered from typhoid, paratyphoid or dysentery may be so engaged until proved by bacteriologic investigation to be free from infection, and every six months those who have been sick must have further bacteriologic and medical examination. Every workman must report sickness in his family. Every person working in a well or reservoir must wear suitable protective clothing and use boots exclusively kept for the work and disinfected as required. No water must be pumped into the supply from any well while work is in progress there, nor must water be returned to the supply until it has been pumped away for a suitable period and its purity confirmed by analysis. If it is not possible to shut down the well during the work precautions must be taken for the effective treatment for water going into the supply.

Pulmonary Embolism Without Arterial Occlusion

At the March 11 meeting of the Société médicale des hôpitaux five necropsies were reported by Drs. Ameuille, Fauvet and Monsaingeon in which pulmonary embolisms, three following operation, one a delivery and one a phlebitis, were observed. Two of these cases appear to confirm previous experimental work by other investigators in showing that actual obstruction of a pulmonary artery is not necessary to have the well known clinical picture of pulmonary embolism. In all five of the cases, such a diagnosis had been made. The technic employed at necropsy was to inject the pulmonary artery with a gelatin solution colored with carmine, according to the formula of Rondeau du Noyer. In cases of embolism the noninjected area is seen in the form of a cone, the embolus being easily found at the summit of the cone. When this technic is correctly applied, every permeable vessel is completely injected up to its precapillary portion. Even on microscopic examination the gelatin serves to identify the arteries and enables one to determine whether the particular section is proximal or distal to the obstruction. In two cases, the authors failed to find an embolism. One patient died twelve days after a hysterectomy and the other the same length of time after a delivery. If an embolism existed, it must have been capillary rather than arterial. In the three other cases an embolus was found but microscopic examination of the blocked area showed that the pulmonary parenchyma was the seat of an intense edema with rupture of the alveolar septums. A marked exudation of polymorphonuclear leukocytes was noted in the edematous areas. The authors found that even in the most severe forms of pulmonary embolism the arterial obliteration plays a relatively unimportant part, which they believe is an argument in favor of the "nervous" or "shock" theory as maintained by French investigators.

At the March 25 meeting of the same society, Drs. Villaret, Justin-Besançon and Bardin, who have studied pulmonary embolism experimentally, stated that there appear to be two opinions on the etiology of this dreaded complication. According to one group a neurovegetative shock is responsible, whereas the other group, basing their opinion on necropsies, believe that there is a mechanical obstruction or occlusion of a pulmonary artery.

Pulmonary embolism presents one of three clinical pictures. In the first, the interval between the appearance of the symptoms and death varies from immediate to several days. In a second type the signs are purely local and recovery may ensue. In the third, the condition may be a latent one because only minute branches are involved.

Cases like those reported by Ameuille, in which no obstruction was found, constitute a new chapter. It becomes necessary to divide cases, all of which present the familiar clinical picture of pulmonary embolism, into those with and those without demonstrable obstruction. The syncope, anxiety, acute edema and cardiovascular collapse seen in both of these are of neurovegetative origin and are observed in conditions other than pulmonary embolism such as angina pectoris.

Cyanosis After Use of Sulfanilamide-like Preparation

At the March 11 meeting of the Société médicale des hôpitaux a case was reported by Drs. Soulié and Moret in which an alarming degree of cyanosis followed the administration, for an acute otitis, of di (p-acetylaminophenyl) sulfone. Slight cyanosis is very common but a severe degree such as they observed is infrequent. The patient was a boy, aged 15, who presented symptoms, following an attack of influenza, of bilateral otitis media necessitating paracentesis. A total of seventeen tablets, each containing 0.5 Gm. ($7\frac{1}{2}$ grains) was given

over an interval of four days. After the ingestion of four tablets, the first day, a marked cyanosis of the lips, nose, nails and skin was noted by the parents, who continued however to give the drug. During the following forty-eight hours additional symptoms in the form of severe retrobulbar pain, palpitation, dyspnea and fatigue appeared. On the fourth day the cyanosis was generalized and extreme. Spectroscopic examination of the blood revealed the presence of methemoglobin but there were no accompanying alterations of the red cells and leukocyte formulas. The cyanosis gradually lessened following cessation of the use of the drug. The case emphasizes the necessity of daily surveillance of all patients who are given these newer preparations, especially when employed to combat acute infections.

Chronic Nephritis, Hyperparathyroidism and Skeletal Changes

An unusual association of chronic nephritis, hyperparathyroidism and skeletal bone changes was the subject of a paper read at the March 11 meeting of the Société médicale des hôpitaux of Paris by Prof. Paul Carnot and Dr. Abel Lafitte. A woman aged 67 when first seen by them in 1937 had had a marked albuminuria and high blood urea content seven years before. This evidence of chronic nephritis had improved, following diet and rest, to such an extent that the patient was able to resume work. In July 1936 she experienced severe pain in the dorsolumbar region of the spine and a recurrence of the albuminuria and high blood urea. Tuberculosis of the spine was suspected but only a moderate osteoporosis of the vertebrae was found. The albuminuria in September 1936 rose to 15 Gm. per liter and the blood urea to 300 mg. per hundred cubic centimeters. On admission to the service of Professor Carnot she had a marked asthenia and pallor, 65 per cent hemoglobin and 2,640,000 red cells. The white cell count was about normal. The blood pressure was 160 systolic, 80 diastolic. No signs of uremia were present. X-ray examination revealed an advanced decalcification involving the dorsal and lumbar vertebrae, pelvis, ribs and clavicles. There was a slight diminution of the alkali reserve of the blood and a moderate hypercalcemia. The phosphorus content of the blood was normal but there was a hyperproteinemia and hypercholesterinemia. Death in April 1937 was preceded by bronchopneumonia. At necropsy, advanced renal sclerosis was found and a large left parathyroid, which on histologic study revealed a diffuse adenoma. The right parathyroid was found in the parenchyma of the thyroid and was normal. The ribs, pelvis and spine showed an advanced degree of decalcification. The osteomalacia was associated with osteoporosis of a fibrocystic type. The skeletal changes appeared to be in an intermediate stage between those of an osteoporosis and those of a von Recklinghausen disease.

The relation between nephritis and skeletal changes has been reported in the literature with the usual explanation that an acidosis of renal origin was directly responsible for the osteoporosis. These osteopathies of renal origin appear to differ from those observed in hyperparathyroidism. In the former there is usually a hypocalcemia and in the latter a hypercalcemia. The presence of an adenoma of the parathyroid probably explains the osteomalacia in this case, but the relations between skeletal changes, chronic nephritis and hyperparathyroidism are complex and relatively few reports of this triple relation have appeared.

Hemorrhagic Ulceriform Cancer of the Stomach

At the March 11 meeting of the Société médicale des hôpitaux a case was reported by three of Professor Gosset's co-workers, Drs. Guttmann, Charrier and Bertrand, illustrating the early diagnosis of cancer in a type of gastric ulcer to which the term "cancer ulcéiforme" is applied at Dr. Gosset's clinic. The cancer ulcéiforme is a primary gastric cancer which has the

anatomic, radiologic and symptomatic characteristics of a chronic benign gastric ulcer. A man aged 50, whose first symptoms were a severe hematemesis and melena in June 1936 was found a month later by radiography to have a niche on the lesser curvature, 3 cm. from the pylorus, which was diagnosed as a benign gastric ulcer. A second radiographic examination, seven months later, showed a persistence of the niche surrounded by changes which Dr. Guttman has termed "aspect encastré"; i. e., with sharply demarcated edges. The patient's general condition appeared so good that no operative procedure was deemed indicated. A second severe hematemesis however took place in June 1937, and films taken three months later not only showed persistence of the niche but a rigid condition of the edges of the ulcer. The patient was seen for the first time in September 1937 by Dr. Guttman and a diagnosis made of ulceriform cancer. He advised operation after two months of medical management had shown no radiographic changes in the ulcer. At operation by Dr. Charrier, an ulceriform lesion the size of a dime (18 mm.) was found, histologic examination of which by Dr. Bertrand confirmed the diagnosis of a primary ulceriform cancer. At the International Gastroenterologic Congress held in the fall of 1937 at Paris, attention was called by Dr. Guttman to the slow evolution of the radiologic signs in such cases as compared with the mild character or even complete absence of all clinical symptoms. One should be cautious in terming an ulcer cured because of the recession of clinical symptoms.

The Sleeping Habits of Twins

In the summer of 1936 a camp for twins, the first of its kind, was established on the Baltic coast. Dr. Horst Geyer of the Kaiser-Wilhelm Institute of Anthropology, Berlin-Dahlem, director of the camp, has reported his observations of his charges in *Forschungen und Fortschritte*. He considers the sleeping habits of twins worthy of special study: Is it possible, by means of usual methods of research on twins, to observe hereditary traits manifested while the consciousness is more or less obliterated by sleep? It was expected that a study of this problem would shed light also on certain especially conditioned psychic functions manifested during consciousness. The experiments were based on recent observations of the function of certain portions of the cerebral axis.

At the camp there were twenty-six female pairs of twins, one half of them enzygotic, ranging in age from 6 to 14 years. These children were observed nightly every two hours from 10 p. m. to 6 a. m. by investigators who went about the sleeping quarters. It is a principle of research on twins that comparative studies of enzygotic and dizygotic twins can provide indications of the degree of hereditary conditionality only if the traits investigated present, in general, variations among the population as a whole. However, few accurate studies have been made of divergent behavior during normal sleep. Geyer's observations at the camp established that great individual variations exist in the regulation of tonus during sleep. The author divided the sleeping children into two groups: the tonus-stable group, which maintained a more or less constant tonus, whether increased or diminished, throughout sleep and the tonus-labile group, which presented obvious fluctuations in tonus. These tonic variations were shown to be completely conditioned by heredity, although they may to a certain extent be modified by environmental influences. Further observations of the sensorimotor behavior during sleep lead to the differentiation of two types of slumber: cortical sleep and axial sleep. If the cerebral cortex is dormant and the cerebral axis in a state of relative wakefulness, namely, when consciousness is plainly obliterated and dreams are absent, the subject will usually manifest rhythmic oscillatory movements. The opposite type of sleep,

axial sleep, inhibits physical movement of the sleeper so that the relative wakefulness of the cerebral cortex is manifested in somniloquence, dreams and so on. The author's experiments revealed an unequivocal hereditary conditionality. The same principles appeared to govern behavior such as somnambulism, nocturnal enuresis and gnashing of teeth.

All investigated phenomena of sleep, in which the cerebral axis takes part (tonus during sleep, position assumed, redness of the cheeks, cortical and axial sleep, respectively) were found, as the author had anticipated, to be strongly conditioned by heredity. Psychic influences were also observed to be present in some measure.

The awakening is astonishingly similar, even to minute details, in a pair of enzygotic twins, whereas, conversely, dizygotic twins exhibit a lack of correspondence in this regard. Some of the children, for example, would awake abruptly with a start, whereas in others awakening was characterized by a period of somnolence. But the hereditary relationship of these different patterns of awakening was easily demonstrable.

The Sickness Insurance Clubs

The steadily mounting number of employed persons had as its corollary further important additions to the membership of the compulsory sickness insurance clubs during 1937. According to figures just released by the national bureau of statistics the number of members in such organizations averaged 20.3 million for the year (not included in this report were the so-called supplementary clubs, to which belong a large number of clerical employees in intermediate positions and so on). The foregoing figure represents an increase of 0.9 million members as against 1936 and an increase of 3.3 million members as against 1933. The income paid into these clubs has increased at a greater rate than the membership, chiefly as the result of the average increase in wages. Premiums exacted by the sickness insurance clubs remain in the same proportion to wages. The aggregate income of the clubs amounted to 1,438 million marks, 9.2 per cent more than in 1936. Reckoned per individual member the total income is estimated to have risen 5 per cent, the income from contributions 5.1 per cent.

Chiefly because of the influenza epidemic at the beginning of 1937, the claims for benefits from these societies was greater than in 1936. Altogether 9.10 million persons incapacitated by illness received benefits from the clubs (exclusive of the supplementary clubs, as mentioned); per hundred members, 41.7 were sick enough to claim disability in 1937 as against 41 per cent in 1936. Administrative expenses have increased at a greater rate than expenditures for claims. In particular, there has been an increase in cash benefits (disability allowances and so on during sickness) and this may be attributed to the widespread increase in wages. Aggregate disbursements of the clubs amounted to 1,419 million marks, namely, an 8.5 per cent increase over the 1936 figure (the increase in disbursement is thus somewhat less than the increase in income). The disbursement per member increased from 67.17 marks to 70.13 marks.

According to this report the excess of the clubs' income over expenditure was around 18 million marks in 1937 as against 9 million marks in 1936.

The Army Ration

The chief of army commissariat recently submitted to the national ministry of war a general report on the nutrition of German troops. Because of the strain of military life, the soldier's food must be of even higher nutritive value than that of the heavy laborer. Whereas the average nutritional requirement of the German civil population in 1936 and 1937 was estimated at 3,159 calories a day, that of the soldier in peacetime was reckoned at 3,880 calories and that of the soldier in the field at 4,258 calories. The war time ration of the civil population, based on that of the war year 1917, was estimated at

1,932 calories; the average consumption in the years preceding the war was 3,190. To improve the entire commissariat, experimental kitchens have been established in each military district. These kitchens will serve as centers of special instruction for commissaries and army cooks. The military authorities are particularly desirous that the troops should be rationed according to a carefully planned economy of food-stuffs. If experience has shown that the men reject certain types of food, these should be omitted from the rations, but exceptions must be made of foods which in the interest of national economy should form part of the fare and to which the men should accustom themselves.

Whereas the civil population has to a certain extent substituted other foods for bread, in the army commissariat bread still occupies its old position. Now, as before, the soldier's bread is a black bread from highly milled flour. With respect both to nutritional value and to palatability, it is recognized as superior to all other breads. The daily potato ration per soldier is from 1,000 to 1,500 Gm. A too heavy meat diet is avoided and generous quantities of fish are served. The men are also habituated to diets rich in vegetables. All in all, the army is accounted the greatest consumer of foodstuffs in Germany.

Proposed Law to Control Venereal Disease

Prof. Eduard Neuber has proposed the enactment of a law which would provide means to check the ravages of venereal disease in Hungary. At a recent meeting of the Hungarian upper house, he said that there is every reason to take the strongest measures against venereal disease. Our statistics do not show the whole truth, because only those patients figure in the statistics who present themselves voluntarily for treatment. In the future methods must be put in effect which will search out all venereal patients. Systematic examinations must be introduced in the high schools, universities and the army, especially at the time of admission, because only a wide search for cases can eliminate the foci of infection. The more important principles of the law he proposes are as follows: The law shall contain regulations extending to all phases of the campaign against venereal diseases. It shall determine the type of cases compelled to be treated. The law shall provide punishment for infecting another person. It shall contain provisions for the protection of marriage and the family, and a program for the development of the health of the race. It shall describe the obligations of physicians with regard to the campaign against venereal disease. It shall prescribe punishment for neglecting to be treated. It shall deal with raising the age limit for the protection of girls, and with other moral and health protection questions of preventive character. The campaign shall be carried on by the department of public health and social welfare. In recent years, with the help of the ministry of the interior, thirty venereal dispensaries have been established and seventy more are needed in order that the law may be made effective.

A Review of Seven Hundred Takata Reactions

At a recent meeting of the Budapest Interhospital Association, Dr. B. Both reported on a study of 700 Takata reactions. A positive reaction was obtained in sixteen of nineteen cases of hepatic cirrhosis. In cases of hepatitis caused by arsphenamine and syphilis the reaction was strongly positive in nine of twenty-two cases and weakly positive in three cases. Among twelve cases of acute nephritis only four reactions were strongly positive, while in the cases of chronic nephritis Both always obtained negative or slightly positive reactions. In circulatory disturbances the reaction was positive in 8.7 per cent of the cases. In a miscellaneous group of maladies the reaction was positive only exceptionally. In his opinion, in reporting a positive

reaction, one should take into account not only the number of tubes showing a precipitate but also the quantity of the precipitate. He illustrated the changes taking place in the precipitates in the form of a curve and exhibited several curves which proved that the Takata reaction is helpful in the differentiation of diseases of the biliary ducts from those of the parenchyma of the liver.

Enlarged Tonsils in Prematurely Born Children

Dr. Brander made studies of 373 prematurely born children who are now from 7 to 15 years old. He studied the size of the tonsils and the pharynx and made intelligence tests according to the method of Binet-Simon-Terman. The results of his analyses indicated that the greater the degree of hypertrophy of the tonsils, the more evident was weakmindedness. He thinks it is probable that hypertrophy of the tonsils and the lack of intelligence had a common cause in the premature birth of these children. In the cases of simple hyperplasia, removal of the tonsils of school children may bring about improvement, but in the cases of weak mindedness it cannot.

AUSTRALIA

(From Our Regular Correspondent)

March 15, 1938.

Public Health in the Fiji Islands

The Fijian colony has an area of about 7,000 square miles and consists of many islands of volcanic origin in the South Pacific Ocean, with Sydney almost 2,000 miles away and Auckland at a distance of over 1,000 miles. Yet it has an excellent public health administrative authority with an enthusiastic medical staff and a central medical school at Suva. Medical practitioners are being trained at this medical school in Fiji and the neighboring island groups, and already two volumes of the "Native Medical Practitioners" have been published, a medical journal which contained in the issue for January 1937 twenty papers on local diseases.

CENTRAL MEDICAL SCHOOL

The Central Medical School has a director of clinical studies—Dr. T. Clunie. The principal of the school is Dr. W. Hoodless, with Dr. C. M. McPherson as pathologist to the government. The objective is to train selected students as native medical practitioners. Students are attracted from the Gilbert and Ellice islands, Cook islands, Loaga and Western Samoa, where each of these administrations is patiently building up a native medical practitioner service at the average rate of one qualified man per annum in each island. The medical authorities intend to provide also postgraduate courses. Already there are three postgraduates attending these classes, and forty medical students have been registered at the medical school. Proper physical training is organized, the importance of which for the native students cannot be overemphasized. Their hours of duty are long, and they are constantly in association with all kinds of diseases; in Suva they are unable to indulge in the regular swimming exercises to which they are accustomed in their respective island homes. Vacations are arranged to fit in where possible with the exigencies of students traveling to and from places like the South Sea islands. Thus a true endeavor is made to inculcate the spirit of friendly relations and assistance between the islands of the Pacific.

PUBLIC HEALTH ADMINISTRATION

In a population of 202,000, made up of 100,000 Fijians, 85,900 East Indians, 5,000 Europeans, 3,800 half-castes, 2,500 Rotumans, 2,000 Polynesians, 1,500 Chinese and 1,400 "others," the registered births totaled 7,330, a ratio of 15.3 per thousand with an infant mortality of 95.1 per thousand births. The Sisters in charge of the obstetric ward of the Colonial War Memorial Hospital are doing excellent work in maternity and child welfare work. There is a successful antepartum clinic in connec-

tion with the hospital, which is largely used by the Indian community. At the instigation of the Rockefeller Foundation authorities, bore-hole latrines were installed and have proved successful in Fiji, but periodic inspection is essential to their maintenance. A beginning has been made toward routine inspection of both houses and water supplies in the Suva and Rewa sanitary districts. Town planning and building regulations are receiving consideration, and an improvement is gradually appearing in the types of buildings erected. Inspection of meat, other foodstuffs and dairies is being instituted, but there is a serious deficiency in qualified sanitary inspectors. Routine medical inspection of incoming vessels is made. A careful watch is maintained for anopheles mosquitoes—a matter of vital importance to Fiji, which is, as yet, a nonmalarial country. None of the rats caught in the port and municipal areas of Suva showed any evidence of plague infection. Hospitals are established at Suva, Lautoka, Lambasa and Levuka, with some provincial hospitals, in all of which a large number of both inpatients and outpatients are treated. Native medical practitioners are in charge of the dispensaries, where about 37,000 patients were treated in 1935. There were 109 cases of typhoid reported in 1935, all of which were proved bacteriologically to be *Eberthella typhi* infections. Mass TAB inoculation of the population is being carried out. Dysentery also was prevalent. The hookworm campaign inaugurated by the Rockefeller Foundation in 1922 has been taken over by the Suva medical department; 5,897 patients were treated with carbon tetrachloride and tetrachlorethylene. It has been stated that the infection has been reduced by half since the commencement of the campaign. Patients with leprosy are segregated at the Leper hospital on the island of Makongi, where the total leper population is now 575. A new building is being erected to enable the laboratories to cope with all essential routine pathologic and bacteriologic work of the islands.

Medical Examination of Recruits

Attention has been drawn to the importance to the community of the problem of medical examination of recruits for military service by Major-General R. M. Downes, director of military medical services in the commonwealth. General Downes discussed several problems of the medical examination. It was decided that x-ray examination of the chest was desirable but would probably be impracticable, that varicocele and undescended testis should not be regarded as great disabilities, and that, while no general rule could be laid down, cardiac efficiency tests often gave an indication of early unfitness. Dealing with defects of the feet it was stated that, while men with flat feet might be quite efficient in civil life and in the performance of sport and athletics generally, they broke down when they had to do much marching or standing, as they would have to do under active service conditions.

Almoner Services in Australia

Australia is gradually developing an almoner service in conjunction with the extension of hospitalization. It is the duty of these almoners to act as liaison officers between the ex-patient at home and the doctor in the hospital. Their chief function is to see that the medical treatment is carried out. In 1929 an institute of hospital almoners was formed in Victoria. As a result of the education carried out under its auspices, trained almoners have been sent from Victoria to other states of the commonwealth. Recently an institute of almoners has been formed in New South Wales. The objects of the institute are to select and train suitable candidates for the work of hospital almoners, to keep a register of trained almoners, and to extend and develop the work of their members. Candidates to be trained for the vocation must be 19 years of age before they begin their course, and no certificate is awarded to students under the age of 22. The course of study comprises a two years course of training in social work with a school of social study recognized by the institute as providing a suitable course. In addition, one year's

training in hospitals is carried out under the direction of experienced almoners. Trainees also attend lectures on the social implications of disease and tutorial classes in the principles and practice of hospital social work.

March 12, 1938.

The National Food Supply in War Time

The minister of agriculture has recently created an official bureau the function of which shall be to study the nation's war-time food supply. By the creation of this bureau, which resulted from a report submitted to the ministerial council by the Preparation for Economic Defense Commission, the conservation of the food supply and the methods of rationing are united under a single administration. The chief duty of this bureau shall be to plan for national use of the food supply in case of mobilization, danger of war and international tension. It was plainly demonstrated during the war years 1914-1918 that the lack of well organized food administration invariably led to a shortage of necessities. Because of diverse economic factors, the supply of essential foodstuffs is now much more adequate than in the prewar years. Since the relief centers, established to combat the depression, are most of them well supplied with necessities, they would become of great importance to the program of an emergency food administration.

Tercentenary of Clinical Instruction at the University of Leyden

Apropos of the tercentenary of the establishment in 1637 of the academy of clinical instruction at the University of Leyden, one recalls that this was the center from which, inspired by Boerhaave, numerous medical scholars set out to establish similar centers at Vienna (van Swieten and Albrecht von Haller), Edinburgh (Rutherford), Pavia, Prague and Rome.

As to the first instruction at the patient's bedside, although certain controversial authors place it in Italy around 1600, the method seems to have originated at either Leyden or Utrecht. In any event, certain it is that after several unsuccessful attempts by Jan van Heurne at Leyden, his son Otto obtained from the university's trustees in 1663 permission to have placed at Otto's disposal "a clinic of twelve beds and a dissection room for cadavers" wherein he might conduct practical lessons twice each week.

Boerhaave and Schacht made the Leyden clinic renowned throughout Europe. Subsequently the clinic underwent a certain deterioration but recently it has once more become a great clinical and laboratory center and is called Boerhaave Center in honor of the great master's memory.

Marriages

THOMAS CAMPBELL GOODWIN, Baltimore, to Dr. MARY STEWART HOOKE of New York, February 1.

WILLIS CADWALADER GERHART, Bala-Cynwyd, Pa., to Miss Eliza Morton of Devon, Pa., February 12.

WILLIAM HAYNE FOLK, Spartanburg, S. C., to Miss Alice Ruth Reeves of Union in February.

PHILIP I. BURACK, New York, to Miss Jessie Wachenheim of New Rochelle, N. Y., February 10.

ROBERT J. MEARIN, Syracuse, N. Y., to Miss Beatrice Bany of New York in December 1937.

RICHARD B. NICHOLLS, Norfolk, Va., to Dr. H. AURELIA GILL of Greensboro, N. C., April 1.

PAUL A. HARPER to Miss Cornelia Esther Edwards, both of Bridgeport, Conn., April 29.

IRVIN S. MILLER, Colton, Calif., to Miss Catherine Harrison at Frederick, Md., recently.

JULES D. GORDON to Miss Cynthia Hymanson, both of New York, April 24.

Deaths

Edward Martin ☉ Media, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; emeritus professor of surgical physiology at his alma mater; professor of clinical surgery, 1903-1910, and John Rhea Barton professor of surgery, 1910-1918; at one time clinical professor of surgery at the Woman's Medical College of Pennsylvania; member of the American Surgical Association, Society of Clinical Surgery and the American Association of Genito-Urinary Surgeons; past president of the Clinical Congress of Surgeons of North America; one of the founders, and for many years a member of the board of regents of the American College of Surgeons; president, and for many years vice president and member of the board of education; formerly commissioner of health of Pennsylvania; director of public health and charities, 1903-1905; veteran of the Spanish-American and World wars; surgeon to the University and Howard hospitals; consulting surgeon to the Bryn Mawr (Pa.) Hospital, Norristown (Pa.) State Hospital and the Wernersville (Pa.) Hospital; since 1895 member of the board of managers of the Swarthmore (Pa.) College; received honorary degrees from the University of Pennsylvania, Swarthmore College and Temple University; aged 78; died, March 17, in the University Hospital, Philadelphia, of carcinoma of the nose and meningitis.

Frederic Jay Cotton ☉ Boston; Harvard University Medical School, Boston, 1894; member of the American Surgical Association and the New England Surgical Society; assistant in surgery at his alma mater, 1902-1904; lecturer on surgery, 1914-1916; associate in surgery, 1916-1919 and instructor in industrial surgery, 1921-1922; formerly lecturer and associate in surgery at the graduate school; assistant professor of surgery at Tufts College Medical School, 1906-1910; veteran of the Spanish-American and World wars; at one time consultant in surgery in the U. S. Public Health Service; a founder and fellow of the American College of Surgeons; consulting surgeon to the Boston City Hospital, Faulkner Hospital, Beth Israel Hospital and the New England Hospital for Women and Children, Boston, Symmes Arlington Hospital, Arlington, Chelsea Memorial Hospital, Chelsea, Quincy (Mass.) City Hospital and Cape Cod Hospital, Hyannis, Mass.; author of the well known book "Dislocations and Joint Fractures"; aged 68; died, April 14, of heart disease.

Thomas James Orbison, Los Angeles; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the California Medical Association; past president of the Los Angeles Society of Mental and Nervous Diseases and the Southern California Academy of Criminology; fellow of the American College of Physicians; at one time a practitioner in Philadelphia; was assistant instructor of mental and nervous diseases at his alma mater; formerly on the staffs of the Polyclinic Hospital and Orthopedic Hospital, Philadelphia; formerly professor of applied therapeutics, University of California Medical School; veteran of the Spanish-American and World wars; on the staffs of the Los Angeles County and Children's hospitals; awarded Baltic Cross and Latvian Jubilee Medal; aged 71; died, March 26, in Sawtelle, Calif.

James Wright Putnam ☉ Buffalo; University of Buffalo School of Medicine, 1882; professor of neurology, emeritus, at his alma mater; member and past president of the American Neurological Association; foreign corresponding member of the Société de Neurologie de Paris; formerly consulting neuropsychiatrist to the U. S. Public Health Service and consultant to the Providence Retreat; neurologist to the Buffalo City, General and the United States Marine hospitals; trustee to the Buffalo Seminary; aged 77; died, March 23, of coronary thrombosis.

Isidor P. Strittmatter ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1881; past president of the Philadelphia County Medical Society; in 1923 established the Strittmatter Award to be given to the physician presenting to the Philadelphia County Medical Society the most valuable contribution to the healing art in any given year; it was awarded for the first time in 1933; on the courtesy staff of St. Mary's Hospital; aged 77; died, April 14, of valvular heart disease and diabetes mellitus.

Ralph Cleaves Wiggin, Brookline, Mass.; Boston University School of Medicine, 1900; professor of genito-urinary surgery at his alma mater; member of the American Urological Association; served during the World War; fellow of the American College of Surgeons; formerly surgeon-in-chief to the Massachusetts Memorial Hospitals; consulting urologist to the Westboro (Mass.) State Hospital; aged 60; died, March 6, in the Captain John Adams Hospital at Soldiers' Home, Chelsea.

Henri Phillip Linsz ☉ Wheeling, W. Va.; Jefferson Medical College of Philadelphia, 1894; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association in 1918, and from 1920 to 1930; past president of the West Virginia State Medical Association; for many years a member of the board of education; on the staffs of the Ohio Valley General and Wheeling hospitals; aged 68; died, March 13, of pulmonary edema.

Willard D. Haines ☉ Cincinnati; Medical College of Ohio, Cincinnati, 1884; member of the House of Delegates of the American Medical Association, 1921-1924; member and past president of the Western Surgical Association; fellow of the American College of Surgeons; professor emeritus of clinical surgery at the University of Cincinnati College of Medicine; on the staffs of the Good Samaritan, Christian R. Holmes and Cincinnati General hospitals; aged 75; died, April 21, of cerebral hemorrhage.

William Stone Jordan, Fayetteville, N. C.; University of North Carolina School of Medicine, Chapel Hill, 1906; member of the Medical Society of the State of North Carolina; past president, vice president and secretary treasurer of the Cumberland County Medical Society; formerly member of the board of trustees of the city schools and county physician; aged 53; on the staff of the Highsmith Hospital, where he died, February 24, of subacute bacterial endocarditis and malaria.

William Kemble Walker ☉ Phoenixville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; member of the American Neurological Association and the American Psychopathological Association; professor of psychiatry at the University of Pittsburgh School of Medicine, 1910-1927; formerly on the staff of the Western Pennsylvania Hospital and St. Francis Hospital; aged 70; died, March 24, in the University Hospital, Philadelphia.

Leslie C. Sammons, Shelbyville, Ind.; Homeopathic Medical College of Missouri, St. Louis, 1899; member of the Indiana State Medical Association; president of the Indiana State Board of Medical Registration and Examination; past president of the Shelby County Medical Society; served during the World War; on the staff of the W. S. Major Hospital; aged 61; died, February 25, of carcinoma.

Lewis Bradley Bibb ☉ Major, M. C., U. S. Army, Atlanta, Ga.; University of Texas School of Medicine, Galveston, 1908; entered the medical corps of the U. S. Army as a first lieutenant in 1920; served during the World War; promoted to major in 1930; instructor in the national guard; aged 56; died, March 13, in a hospital at Wilmington, N. C., of injuries received in an automobile accident.

Charles Wilbur Mercer ☉ Biloxi, Miss.; Medical College of Virginia, Richmond, 1904; member of the Clinical Orthopedic Society, American Academy of Orthopedic Surgeons and the Missouri State Medical Association; served during the World War; formerly on the staffs of the Trinity Lutheran, St. Luke's and General hospitals, Kansas City, Mo.; aged 57; died, February 28.

Robert Parvin Crawford, Excelsior Springs, Mo.; University of Louisville (Ky.) Medical Department, 1904; member of the Missouri State Medical Association; served during the World War; aged 55; formerly on the staff of the Veterans Administration Facility, where he died, February 17, of tuberculosis.

William Irving Joss, Erick, Okla.; Hahnemann Medical College and Hospital of Philadelphia, 1906; member of the Oklahoma State Medical Association; on the staff of the Erick Hospital; aged 67; died, February 21, in St. Anthony Hospital, Oklahoma City of cerebral hemorrhage.

Fred Messenger Lowe, Newton, Mass.; Harvard University Medical School, Boston, 1885; member of the Massachusetts Medical Society; formerly city physician; aged 77; for many years on the staff of the Newton Hospital, where he died, February 28, of pneumonia.

Wayne Le Suer Bridgford ☉ Olympia, Wash.; Cooper Medical College, San Francisco, 1902; formerly member of the city council, mayor and city and county health officer; on the staff of St. Peter's Hospital; aged 59; died, February 22, of coronary disease.

Edward Boston Frisbee, Los Angeles; Tufts College Medical School, Boston, 1909; served during the World War; aged 53; on the staff of the Veterans Administration Facility, where he died, February 21, of chronic cholecystitis and chronic pancreatitis.

Louis Christian Brand, Kwangju, Chosen, Korea; University of Virginia Department of Medicine, Charlottesville, 1923; member of the Medical Society of Virginia; missionary; chief surgeon of the E. L. Graham Hospital, which he founded; aged 43; died, February 28.

William Francis Roberts, St. John, N. B., Canada; Bellevue Hospital Medical College, New York, 1894; minister of health; past president of the New Brunswick Medical Association and the American Academy of Physical Therapy; aged 68; died, February 10.

Karl Franklin Roehrig, Denver; Northwestern University Medical School, Chicago, 1907; member of the Associated Anesthetists of the United States and Canada; on the staff of the Denver General Hospital; aged 52; died, February 20, of coronary thrombosis.

J. Sumner Stone, Wheeling, W. Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; formerly a minister and missionary; aged 82; died suddenly, February 18, in New Rochelle, N. Y., of acute dilatation of the heart.

Edward August Weisenhorn, Teutopolis, Ill.; St. Louis University School of Medicine, 1909; member of the Illinois State Medical Society; aged 55; on the staff of St. Anthony's Hospital, where he died, February 13, of pneumonia.

Maxwell Stevenson Inglis, Vancouver, B. C., Canada; Manitoba Medical College, Winnipeg, 1893; served with the Canadian Army during the World War; at one time provincial coroner in Manitoba; aged 74; died, January 20.

Alexander Aaron Stern ♂ Kingston, N. Y.; Long Island College Hospital, Brooklyn, 1889; fellow of the American College of Surgeons; on the staff of the Kingston Hospital; aged 69; died, February 26, of cardiorenal disease.

Clement Albert Weirick, Longmont, Colo.; Hahnemann Medical College and Hospital, Chicago, 1876; formerly professor of materia medica, emeritus, at his alma mater; aged 85; died, February 2, of acute dilatation of the heart.

Frank Emerson Way, Wahoo, Neb.; Boston University School of Medicine, 1890; past president of the Saunders County Medical Society; on the staff of the Community Hospital; aged 69; died, February 5, of cerebral embolism.

William Henry Terrell, Pittsboro, Ind.; Medical College of Indiana, Indianapolis, 1889; past president of the Hendricks County Medical Society; formerly county coroner and county health officer; aged 75; died, January 12.

Athol Horatio Wedge, Mendota, Wis.; University of Illinois College of Medicine, Chicago, 1916; served during the World War; on the staff of the Mendota State Hospital; aged 44; died, February 28, of myocarditis.

Walter Curtis Galloway, Gaithersburg, Md.; Washington University School of Medicine, Baltimore, 1874; member of the Medical Society of the State of North Carolina; aged 87; died, February 18, of cirrhosis of the liver.

Henry Bascom Weaver, Asheville, N. C.; Washington University School of Medicine, Baltimore, 1872; member of the Medical Society of the State of North Carolina; aged 86; died, February 13, of nephritis.

James Harrison Van Vorhis, Corcoran, Calif.; Northwestern University Medical School, Chicago, 1901; member of the California Medical Association; aged 64; died, February 9, of lobar pneumonia.

Donald Gillies Buchanan, Troy, N. Y.; Albany (N. Y.) Medical College, 1892; member of the Medical Society of the State of New York; aged 68; died suddenly, February 22, of angina pectoris.

John Howard Foster, Weogufka, Ala.; Atlanta College of Physicians and Surgeons, 1910; member of the Medical Association of the State of Alabama; aged 54; died, February 25, of myocarditis.

George Taylor Dawley, New London, Wis.; Rush Medical College, Chicago, 1881; for many years member of the school board and library board; aged 84; died, February 11, of cerebral hemorrhage.

Clayton Chester Ferguson, Newark, N. J.; New York Homeopathic Medical College and Hospital, New York, 1907; aged 70; died, February 2, of cerebral thrombosis and myocarditis.

Harriette D'Esmonde Keatinge, New York; New York Medical College and Hospital for Women, 1883; aged 77; died, February 15, in Pasadena, Calif., of carcinoma of the intestine.

Clinton Eldridge Galloway, Los Angeles; Medical College of Indiana, Indianapolis, 1882; aged 82; died, February 28, of fracture of the hip received in a fall and chronic myocarditis.

Louis Alexander Dewing ♂ Cambridge, Mass.; Medico-Chirurgical College of Philadelphia, 1901; aged 66; died, February 21, of cerebral arteriosclerosis and edema of the lungs.

William Grant Bond Decker, Detroit; University of Michigan Homeopathic Medical School, Ann Arbor, 1897; aged 68; died, February 6, in Willis, Mich., of cerebral hemorrhage.

John Felix Landry, Minneapolis; M.B., Laval University Faculty of Medicine, Quebec, Que., Canada, 1878, and M.D., in 1880; aged 82; died, February 4, of coronary sclerosis.

Walter D. Bennie, Naylor, Mo.; Missouri Medical College, St. Louis, 1890; aged 75; died in February of an infection developing from an injury received in a fall four years ago.

Mary Caroline Mackin Browning ♂ Cortland, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1925; aged 58; died, February 18, of coronary embolism.

Edward H. Zenor, Hawthorne, Calif.; American Medical College, St. Louis, 1904; aged 68; died, February 11, of benign prostatic hypertrophy, hydronephrosis and uremia.

Julius H. Fiegenbaum, Alton, Ill.; Bellevue Hospital Medical College, New York, 1885; formerly city health officer; aged 78; died, February 26, of cerebral hemorrhage.

Edmund Kurt Walter, Montara, Calif.; University of Kansas School of Medicine, Kansas City, Kan., 1920; aged 49; died, February 6, of cardiovascular renal disease.

Joseph L. Black, Hood River, Ore.; Chicago Homeopathic Medical College, 1893; aged 69; died in the Hood River Hospital, February 24, of coronary occlusion.

Lester Everett Cox, Los Angeles; University of Pennsylvania Department of Medicine, Philadelphia, 1898; aged 61; died, February 28, of coronary sclerosis.

William Thane Partridge, Westerville, Ohio; Pulte Medical College, Cincinnati, 1888; aged 79; died, February 19, of hypostatic pneumonia and myocarditis.

William B. Craig, Indianapolis; Medical College of Indiana, Indianapolis, 1893; aged 69; died, February 16, in St. Vincent's Hospital of thrombosis and gangrene.

Charles F. Griswold, Waverly, N. Y.; University of Vermont College of Medicine, Burlington, 1889; aged 71; died, February 5, of mitral insufficiency.

Richard Washington, Claymont, Va.; Columbia University Medical Department, Washington, D. C., 1894; aged 75; died, February 3, of heart disease.

Bennette Auxford Burks ♂ Winter Park, Fla.; University of Alabama School of Medicine, University, 1910; aged 53; died, February 24, of leukemia.

Samuel Russell McCreary, Belleville, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1919; aged 44; died, January 28.

Frank F. Carl, Nichols, Iowa; State University of Iowa College of Medicine, Iowa City, 1886; aged 77; died, February 6, of coronary thrombosis.

David Stockley Sutherland, Halifax, N. S., Canada; Dalhousie University Faculty of Medicine, Halifax, 1925; aged 38; died suddenly, January 26.

James Elbert Adams, Jacksonville, Fla.; University of Nashville (Tenn.) Medical Department, 1903; aged 64; died, February 28, of myocarditis.

John Harold Brooks, Azusa, Calif.; Kentucky School of Medicine, Louisville, 1891; aged 69; died, February 21, of carcinoma of the prostate.

Henry A. Cook, Parrott, Ga.; University of Georgia Medical Department, Augusta, 1883; aged 75; died, February 21, of mitral regurgitation.

Harry Bain Avery, Taghkanic, N. Y.; Cornell University Medical College, New York, 1905; aged 54; died, February 27, of lobar pneumonia.

George Zimmerman, Fremont, Ohio; Chicago Homeopathic Medical College, 1884; aged 78; died, February 7, in Los Angeles of heart disease.

John Charles Bell, Merlin, Ont., Canada; Trinity Medical College, Toronto, 1884; L.S.A., London, England, 1886; died, February 9.

Joseph A. Milroy, Okmulgee, Okla.; Starling Medical College, Columbus, 1898; aged 67; died, February 7, of heart disease.

Harry Ward Hazlett ♂ Paonia, Colo.; Gross Medical College, Denver, 1902; aged 72; died, February 8, of Addison's disease.

Norman Anderson, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1892; died, February 17.

Bureau of Investigation

TWO MINOR MEDICAL FRAUDS BARRED

The Darnell Cure-All and the J. Franklin Walker Swindle Are Served with Fraud Orders

DARNELL'S ORIENTAL KING OF PAIN.—Under the names "L. T. Darnell & Co." and "L. Darnell" one Mrs. Leroy T. Darnell—who had no medical training or qualifications—sold from Manchester and Osborn, Ohio, a preparation called "Darnell" or "Oriental King of Pain." This "patent medicine" seems to have been advertised as a cure for everything from soft corns to hardening of the liver. Specifically it was a "sure cure" for heart affections, rheumatism, catarrh, diphtheria, measles and "falling of the womb"; to say nothing of such antipodal complaints as deafness and piles!

This panacea was on the market for many years. It was originated by the late husband of Mrs. Darnell and when Darnell died some twenty years ago—presumably of some condition that his nostrum would not cure—his widow continued its sale. The Oriental King of Pain was found by government chemists to be nothing more esoteric than cottonseed oil (90%) and volatile oils, mostly eucalyptus (10%).

It was necessary under the law for the Government to introduce competent medical testimony to show that this mixture would not cure diphtheria or tuberculosis; that it had no value in heart affections nor would it cure scarlet fever, malaria, deafness nor "falling of the womb." The Post Office authorities called on "L. T. Darnell & Co." and "L. T. Darnell" to show cause why a fraud order should not be issued against them. No one appeared in Washington to defend the business but a Manchester, Ohio, attorney wrote to the office of the Solicitor of the Post Office Department stating that the respondent "admits the truth of the charges."

According to the official report of the case Mrs. Leroy T. Darnell was the only person connected with the business and she made up the nostrum in, and sold it from, her residence. On September 15, 1937, a fraud order was issued debarring from the mails L. T. Darnell & Co. and L. Darnell.

WALKER MEDICINE COMPANY.—Under this name and also under his personal name, J. Franklin Walker sold through the mails from Cincinnati, Ohio, two "patent medicines" known, respectively, as "Walker's Blood and Skin Purifier or Alterative and Laxative" and "Walker's Uneeda Tonic or Stimulant to Appetite."

One of the circulars put out by Walker read in part:

WALKER'S

BLOOD AND SKIN PURIFIER

Good for Pimples, Pustules, Tetter or Salt Rheum, Tumors, Blotches, Boils, Ringworms, Sores, Ulcerations, Scrofula, Syphilitic Affections, Rheumatism & All Blood and Skin Disorders, Also Female Trouble, Lost Manhood, Nervousness, Poor Appetite, General Rundown, Cannot Sleep.

UNEEDA TONIC

For Indigestion, Heartburn, Water-Brash, Sour Stomach, Nervous Stomach Ache, Gas on Stomach and all Disorders of the Stomach.

Chemical analysis by the government chemists showed that the "Blood and Skin Purifier" was a mixture of herb and root extractives including cascara, sarsaparilla, licorice, yellow dock and mandrake. It was essentially a laxative and not in any sense a cure for syphilis, tumors, "female trouble," "lost manhood," rheumatism and nervousness, as advertised by Walker.

The "Uneeda Tonic" was found to consist mainly of baking soda with small amounts of nux vomica, belladonna, peppermint and alcohol in water. This, the government officials declared, would not cure indigestion, nervous stomach-ache and all disorders of the stomach, as declared by Walker.

When J. Franklin Walker appeared in Washington to answer the charges brought against him he agreed to execute and file an affidavit providing for the issuance of a fraud order against the "Walker Medicine Company"—although not against his personal name—and he also stipulated that remittances received under his personal name would be returned immediately to the senders. On June 22, 1937, the mails were closed to the Walker Medicine Company of Cincinnati.

Correspondence

"RECOVERY FROM GONORRHEAL ENDOCARDITIS AFTER ARTIFICIAL HYPERPYREXIA"

To the Editor:—In THE JOURNAL February 19 is a paper by Freund, Anderson and Lilly entitled "Recovery from Gonorrheal Endocarditis After Artificial Hyperpyrexia." In the first paragraph of the second column on page 549 is the sentence "According to the criteria generally accepted, a patient proved to have gonorrheal endocarditis must have a positive blood culture in vivo or a positive culture or smear from the vegetations at necropsy." These criteria, however, as applied to a case in which recovery occurs are entirely inadequate as, in the authors' own words in the second paragraph in the first column on page 550, "A positive blood culture in itself is not definite evidence of endocarditis, for one frequently sees gonococcemia without endocardial involvement. . . . The diagnosis may be obscured by the presence of a chronic valvular disease and may not be detected until the signs of fresh valvular involvement or of embolic phenomena appear."

Immediately following this the authors cite seven cases from the literature which they believe are proved cases of recovery from gonorrheal endocarditis. However, applying the authors' own criteria it appears at once that, with the single exception of case 5, all the other six patients could perfectly well have recovered merely from a gonococcemia.

Case 5 is suggestive of recovery from gonorrheal endocarditis but unfortunately in the brief abstract of the case there is no mention of an examination of the heart prior to three months after the onset of the disease; there is no proof that this patient's diastolic aortic murmur had not been present before his gonococcemia.

In the authors' own case, under laboratory examination, there is a single observation: "63 per cent hemoglobin." There is no statement as to what method was used. Even if this was done by a reliable method such as the Sahli method, an anemia of that degree can cause a loud murmur by itself, particularly if associated with a high temperature and a rapid heart rate.

DUDLEY MERRILL, M.D., Cambridge, Mass.

DOCTORS IN A SOCIAL DIRECTORY

To the Editor:—A firm calling itself the National Social Directory Publishers, 340 North Michigan Avenue, Chicago, is and has been soliciting subscriptions to its Local Social Directories (e. g., New Orleans). Their charge for the latter was either \$2.50 or \$3.

They have delivered what they call the Southern Section, embracing Texas and the thirteen Southern states. Doctors seem to be easy victims. A casual examination of this precious "Social Directory" shows that, with names and addresses, there are in

New Orleans	38 entries	20 doctors
Birmingham	30 entries	19 doctors
Louisville	13 entries	3 doctors
Shreveport	19 entries	3 doctors
Asheville	17 entries	3 doctors
Charlotte	5 entries	3 doctors
Charleston	15 entries	4 doctors
Little Rock	45 entries	6 doctors
Jacksonville	11 entries	6 doctors

For all nine of these representative communities this so-called Social Directory gives the names of 193 families, of whom sixty-seven are doctors. It would appear that this publication is not in any true sense a social directory but simply a list of those who were "stung" by subscribing to what they supposed

would be something like the reputable works of this kind. As sixty-seven of the 193 who were caught in these nine cities were doctors, it has seemed to me that THE JOURNAL might feel inclined to issue a warning to its subscribers.

E. D. FENNER, M.D., New Orleans.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LATENT SYPHILIS—POSSIBLE NEURO-SYPHILIS, TRANSMISSION

To the Editor:—An engineer, aged 26 years, in August 1936 had a blood reaction to the Wassermann, Kahn and Gradwohl tests of four plus. He began treatment immediately. He had no history of any lesions that might have been primary and has never had any symptoms. Other members of his family had Wassermann tests but all were negative. General physical examination and examination of the eyegrounds, reflexes and cardiovascular system all give negative results. He has had intensive, continuous treatment since Aug. 10, 1936, having received twenty doses of 0.06 Gm. of mapharsen at weekly intervals with mercuric salicylate 1 grain (0.065 Gm.) and thiobismol 0.2 Gm. at weekly intervals between the injections of mapharsen. The Wassermann test taken November 23 following this first series was a weak one plus, the Kahn test the same and the Gradwohl test two plus. He then received thiobismol 0.2 Gm. twice a week for seventeen doses and mercuric salicylate 1 grain twice a week for eleven doses up to April 7, 1937. At this time he developed dizziness, intermittent spells of numbness of the fingers of the left hand and lower left leg, stuttering or broken speech and a progressive slowness in grasping a question. He talked relevantly but with a slowing in thought and had the appearance of being startled when questioned. I was informed by his superior officer that he had slowed up considerably in his work. Two years previously he had been badly beaten, struck on the head and left lying unconscious in the street by an unknown assailant. When found, he was taken to the hospital for treatment. He states that he had a bad laceration on the right side of the head. X-ray examination gave no evidence of fracture of the skull. Spinal puncture was made several times and the fluid was bloody but he knows of no tests. He remained in the hospital for several days and was then released and able to resume his employment. When the symptoms developed I did a spinal puncture and the analysis revealed the colloidal gold test 112211000, globulin two plus positive, Wassermann one plus positive and Kahn one plus positive. I then gave him sixteen doses of tryparsamide every five days, starting with 1 Gm. and increasing to 3 Gm., finishing July 13. A blood test August 4 revealed the Wassermann reaction negative, Kahn weak one plus and Gradwohl negative. All symptoms completely cleared following this series of tryparsamide and he was as normal as ever and has remained the same. In view of the still weak positive Kahn reaction I gave him ten more doses of mapharsen, 0.06 Gm. at weekly intervals followed by ten doses of thiobismol 0.2 Gm. weekly, bringing treatment to November 1. The blood test November 16 showed the Wassermann, Kahn and Gradwohl reactions all one plus. Spinal puncture November 20 with analysis of fluid revealed the colloidal gold test 0000000000, globulin normal and the Kahn and Wassermann reactions negative. 1. What promise can I give this man of complete cure? 2. What is the prognosis? 3. What would you suggest regarding further treatment, type of treatment and how often? 4. How soon should he marry? 5. What about having children?

M.D., Wyoming.

ANSWER.—It is impossible to provide definite answers. On the basis of the information furnished, the patient when first seen in August 1936 had latent syphilis. It is unfortunate that the diagnosis of latency was not confirmed at the time by an examination of the spinal fluid. The illness of April 1937 is strongly suggestive of the development of dementia paralytica. While the somatic symptoms and psychic changes might have been caused by other conditions as, for example, chronic alcoholism, nevertheless their disappearance following treatment with tryparsamide lends weight to the belief that they were actually dementia paralytica.

However, this diagnosis is not confirmed by the serologic tests of the spinal fluid performed in April 1937. The statement that the Wassermann and Kahn reactions of the spinal fluid were one plus is meaningless. Serologic tests of the spinal fluid cannot be accurately interpreted except on a quantitative basis and it is essential to know the exact amount of fluid with which the tests were performed. In dementia paralytica the Wassermann test of the spinal fluid is usually strongly positive with very small amounts of fluid; e. g., 0.025 cc. The fact that this spinal fluid was probably incompletely positive may indicate either that the laboratory in which the tests were performed was unreliable or, less probably, that a spinal fluid

originally showing the "paretic formula" had been modified by the treatment already given. The negative spinal fluid examination of November 20 is not helpful in arriving at a diagnosis. It is suggested that the possibility of dementia paralytica be further investigated by means of neuropsychiatric consultation and by means of another examination of the spinal fluid in a different laboratory in which the Wassermann test is performed on a quantitative basis and by the method of ice-box fixation.

In the light of these considerations, the answers to the specific questions asked by the correspondent are as follows:

1. The promise of complete "cure" depends first on the accuracy of identification of the type of neurosyphilis and second on the interpretation that is put on the word "cure"; i. e., whether biologic, symptomatic or serologic. Biologic "cure" in the sense of eradication of the last remaining spirochete is probably completely impossible, as is also serologic "cure." Some degree of persistent positivity of blood, spinal fluid or both may be expected. Symptomatic "cure" is however possible, though the percentage probability of it cannot be accurately stated without further diagnostic information.

2. The prognosis cannot be accurately outlined until the type of neurosyphilis is defined.

3. In view of the strong probability that the patient has had dementia paralytica, even though he may now be in a complete remission, he should certainly be treated at once with artificial fever, preferably with induced malaria. Following the completion of malaria therapy his treatment should be carried on for another minimum period of one year, preferably with tryparsamide and a bismuth compound, given either in alternating courses of from ten to twelve injections each or with tryparsamide given continuously, a course of bismuth being given simultaneously from time to time. The bismuth preparation used should preferably be an insoluble salt suspended in oil or a liposoluble salt rather than the water soluble thiobismol.

4. The question as to how soon he should marry depends, first, on his probable infectiousness for his marital partner which, in view of the suggested diagnosis of dementia paralytica and the large amount of treatment he has so far had, may be discounted, and, second, on his willingness to tell his fiancée that he has had syphilis, so that she may accept or reject whatever risk of infection of herself may exist and whatever risk there may be as to chronic invalidism or death in the patient. Since the risk of infection to her seems to be small, this consideration may be discounted, provided his wife is willing to undergo the examinations mentioned in paragraph 5.

5. It is quite safe for the patient to have children provided he does not infect his wife with syphilis. The disease is never transmitted from father to child but only through the mother. If and when his wife becomes pregnant, the possibility of infection in her should be guarded against by blood serologic tests carried out every four to six weeks throughout the entire course of her pregnancy. If these tests are negative, it may be assumed that she has escaped infection and that the child will be healthy. If, on the contrary, a positive test develops, a healthy child may be obtained by treatment of the mother, provided her treatment is begun early enough in pregnancy.

ALLERGY IN TWINS

To the Editor:—I am preparing an original article based on a study of identical and unidentical twins in one family. The identical twin had the same allergies up to a certain age, but one, for some unknown reason, had progressive asthma and the other lost all evidence of allergy. Are there any other studies of allergy in identical twins reported in the literature?

M.D., New York.

ANSWER.—Spaich and Ostertag (*Ztschr. f. menschl. Vererb. u. Konstitutionslehre* 19:731, 1936) showed that the allergic conditions existing in allergic twins are common to the two twins in from 80 to 100 per cent of the cases. Migraine is common to the two in about 80 per cent of the cases and urticaria in from 66 to 91 per cent of the cases, while asthma is common to the two in from 28 to 58 per cent. In instances in which only one twin is affected there is usually no familial allergy. In asthma of the two identical twins other allergic conditions are not common. In cases of familial sensitization manifested in both twins there is usually multiple allergy, more marked however in girls than in boys. The authors' conclusion is that when one twin is allergic the family history may be negative, but when both are allergic the family history is positive as a rule.

At the 1936 meeting of the Association for the Study of Allergy Bret Ratner read a paper on "Does Heredity Play a Role in the Pathogenesis of Allergy?" (*J. Allergy* 8:273 [March] 1937). Ratner studied 250 allergic and 315 normal

children and their respective families and found the incidence of allergy in the family of the allergic child about the same as in that of the normal child. From 7 to 10 per cent of the total general population are allergic. So-called allergic families in whom a large proportion are allergic are very rare. About 50 per cent of the families, both of allergic and of normal children, show no allergy in their lineage. No conformity with the simple mendelian laws of inheritance in allergic case histories was found. About 5 per cent of the children showed symptoms of allergy in the first year of life; allergic symptoms developed in almost all before the age of 8. Ratner believes that the development of allergy in children is to a large extent due to chance and that a child may become sensitized in the uterus of the mother before birth. Ratner does not believe that susceptibility to allergic diseases is inherited through germ plasma and he therefore hopes that proper preventive measures can be instituted to control and to a large extent eradicate allergic diseases.

In the discussion that followed Ratner's paper much disagreement was evident. Sulzberger felt that it was almost impossible to be scientifically accurate in purely clinical research in human heredity, owing, for one thing, to the uncertainty of paternity. Sulzberger believes in common with the large majority of those doing special work in allergic diseases that in allergic patients the familial incidence of allergic conditions is very much higher than in normal individuals.

As regards the relationship of identical twins and allergy, several allergists mentioned cases. Kahn has a pair of identical twins, one with severe pollen asthma, the other symptom free. Milton Cohen stated that he had several pairs of identical twins with one child showing active allergy and the other no evidence of allergy. On the other hand, Benson discussed two sets of identical twins in which all four patients had severe asthma; Credille, one set with asthma; Fineman's set of identical twins, aged 8, both developed asthma at the age of 4 and both are sensitive by skin tests to the same foods, wheat, mustard and radish, and both give positive skin tests to ragweed without clinical evidence of hay fever.

Tuft (Clinical Allergy, Philadelphia, W. B. Saunders Company, 1937) believes that active fetal sensitization by way of the placenta is a more plausible concept than passive fetal sensitization in utero.

In the literature are many articles on the relationship of heredity to allergic diseases, such as that of Wiener, Zieve and Fries (*Ann. Eugenics* 7:141, 163 [Sept.] 1936).

PAINFUL BREASTS FROM ESTROGENIC SUBSTANCES

To the Editor.—In the course of receiving injections of theelin in oil, a patient with early menopausal symptoms has developed markedly caked breasts or a sort of cystic mastitis. On discontinuance of the theelin, the painful lumps have disappeared for the most part. Is this condition a frequent occurrence? Do you think it would be due to overdosage? Is there any other treatment than stopping the theelin?

W. L. SHARP, M.D., Anderson, Ind.

ANSWER.—It is known that estrogenic substances, of which theelin is one, are responsible for growth and branching of the mammary gland trees, possibly slight stimulation of the alveoli, and development of the nipple. Corpus luteum hormone (progesterone) in the presence of estrogen produces development of the alveoli to a condition resembling that found during the first fifteen days of pregnancy or pseudopregnancy.

Mazoplasia is characterized by a hyperplasia of the periacinous connective tissue, new formation of ducts and acini and desquamation of epithelial cells in the terminal ducts and their acini. The ducts and acini become distended by the exfoliated epithelial cells, giving rise to diffuse and generalized nodularity (lumpy breasts). The most pronounced symptom is a diffuse, aching pain over the whole area of one or both breasts, generally more on one side than on the other. The pain is often worse at menstruation. Women suffering from mazoplasia often show evidence of ovarian hypofunction. The menstrual periods are frequently of short duration and the menstrual flow is usually scanty.

There are some who believe that these painful breasts associated with menstrual disturbance are due to an inadequate amount of estrogen. There is reason to believe that the condition may be due at least in some cases to a high secretory level of estrogen rather than to a hyposecretion of this hormone, though it is frequently relieved by administration of estrogen.

The patient in question perhaps has some follicular development during each menstrual cycle with the production of growth of the gland trees in the breasts. It is quite possible that the amount of estrogen secreted by the follicle during the menopausal disturbance in this patient may stimulate a certain amount of lacteal duct development. The addition of theelin further

stimulates growth of the gland trees and congestion in the breasts, causing them to be painful. It is stated that when the theelin is discontinued the painful lumps have disappeared for the most part. This is evidence that the condition is due to hyperstimulation by the estrogen.

Painful breasts are a rather common occurrence in many young women during the latter part of the menstrual cycle and the condition, while painful, will probably not lead to serious consequences. If the injection of theelin aggravates the condition, perhaps it would be better to give smaller doses (no statement of doses administered was made).

If the patient needs estrogen to relieve menopausal symptoms and if small doses (say from 50 to 100 rat units three times a week) cause pain, perhaps the pain might be relieved by local application of heat or some mild analgesic.

HEADACHE

To the Editor.—A man, aged 59, has always enjoyed good health except for pneumonia followed by a lung abscess with complete recovery five years ago. For the past three months he has been getting sudden headaches following coughing, sneezing or at times quick movements of the head. The pain is over the left frontal and temporal regions, with the greatest point of pain near the vertex. The pain is quite sharp, somewhat throbbing in character and moderately aggravated by activity. It is relieved promptly by acetylsalicylic acid and related compounds or will disappear gradually in about one hour if he lies down. The headaches do not follow any regular periodicity, never are present on awakening, may occur several times in one day or may not occur for several days, depending on the presence of the mechanical factors of production. The patient is thin, though well nourished, vigorous and active and is of a somewhat nervous temperament. The temperature is 98.6 F., the pulse 72 and the blood pressure 134 systolic, 76 diastolic. Examination of the head reveals that the ears, eyes and pupillary reflexes are normal. The septum is slightly deviated. The turbinates are normal. There is no discharge. There are no polyps. The tonsils are apparently normal. The teeth appear to be in good condition. The frontal and maxillary sinuses are not tender to pressure and transilluminate clearly. There are no neuralgic spots on the scalp. The heart, lungs, abdomen, spine and extremities are essentially normal except that the deep reflexes are exaggerated. No pathologic reflexes, palsies or disturbances in sensation were noted. The patient feels perfectly well except for this complaint. He eats well, he has no dyspepsia, the bowels are regular and there are no genito-urinary complaints. Sleep is also normal. Urinalysis, blood count and blood Wassermann tests are normal. No x-ray studies of the sinuses or sella turcica have as yet been made. I will greatly appreciate any suggestions that you may be able to make which may point to a diagnosis and the alleviation of this unpleasant condition.

FREDERICK S. TABER, M.D., New Brunswick, N. J.

ANSWER.—Coughing and sneezing produce a sudden interference with the venous return from the head. This engorgement of the veins results in increased intracranial pressure, and the shock of the sudden interference is directed against the gasserian ganglion or its branches. For this reason coughing or sneezing may aggravate any headache or precipitate a latent one. The problem in this instance would appear to be that of determining why these nervous structures are abnormally sensitive to such impulses. Since this history does not indicate intracranial disease, arteriosclerosis or chronic fatigue, the ethmoid sinuses should be examined. Inflammation there has been known to give rise to such phenomena. The sphenopalatine ganglion may be treated with ephedrine or cocaine to determine its possible participation in the syndrome. Symptomatic treatment with bromides and salicylates may give considerable relief if taken regularly for two or three weeks.

INJECTION OF VAS DEFERENS

To the Editor.—Can you give me any information on the solution used for injection into the vas deferens for prostaticism? The method is used in this section with considerable success but I have been unable to find out the chemical nature of it.

M.D., Neb.

ANSWER.—There has been no serious consideration of the possible therapeutic value of operations on the vas deferens in prostaticism since the turn of the century, at which time a temporary interest in castration and vasectomy actually hindered progress in the sound surgical cure of this condition. Vas ligation is now employed only as a preliminary step in the preparation of a patient for prostatectomy. There are instances, only too well known, wherein this minor preliminary step has been offered as the complete cure to patients and large fees have been collected for a procedure worthless except to ward off epididymitis. The treatment of prostaticism has developed logically and gradually and the approved methods can be studied from any one of the many excellent modern textbooks, in which one will fail to read of injections into the vas deferens being of temporary or permanent value in controlling symptoms.

Injections of the vas deferens are used occasionally in the treatment of stubborn cases of chronic vesiculitis and the asso-

ciated prostatitis. A solution of from 1 to 2 per cent mercuriochrome or 5 per cent collargol, 5 cc., is injected into the lumen of the vas deferens through a surgically clean wound. Care must be taken that the solution enters the vas and is not injected into the fascial layers of the cord. The possibility of sterility from occlusion of the vas following this procedure must be reckoned with when offering it as a possible therapeutic measure.

"CARBITOL"

To the Editor:—It has recently been brought to my attention that some of the pharmaceutical preparations of the George Breon Company, within the last few months, contained a derivative of diethylene glycol, called carbitol, in concentrations ranging roughly from 3 to 15 per cent. The company's detail men as well as federal agents are now engaged in gathering up the lots dispensed in this territory, which contained the carbitol. I have had the misfortune of dispensing about two thirds of a gallon of a cough preparation called bellamphor, chiefly to children. I am now engaged in checking back and collecting unused material and fortunately have observed no toxic manifestations as yet.

A. C. R., M.D.

ANSWER.—Other inquiries have come to the attention of the office of the Council on Pharmacy and Chemistry. The following communication was sent to Breon & Co. by the Secretary of the Council:

There has been received in this office correspondence from physicians stating that some of the preparations of Geo. A. Breon & Co. within the last few months contained a derivative of diethylene glycol called Carbitol.

One of these preparations, it has been stated, was Bellamphor. Will you kindly state for the information of THE JOURNAL what preparations of Geo. A. Breon & Co. have contained diethylene glycol, or carbitol, or similar substances used as solvents?

A letter signed by the firm's laboratory director states:

None of our preparations contain diethylene glycol. The mono-ethyl ether of diethylene glycol, known under such trade names as "Gly-Ketol" and "Carbitol," was used as a solvent in five preparations until November 1, 1937. The period of such use was seven and one half years. In further reply to your inquiry of December 22, no other derivative of diethylene glycol has been used by us.

Carbitol is listed by its manufacturers, the Carbide and Carbon Chemicals Corporation, under the head of "Alcohols-Ethers" and has been recommended for use by at least one reputable distributor as a solvent in pharmaceuticals for human consumption for the past ten years. During the years that we used the substance, we have no record of receiving a report of and do not recall a single instance of any harmful effects being associated with it.

The five preparations, the percentage of Carbitol contained, and the therapeutic doses were:

Bellamphor, 5.1%; 1 to 1½ teaspoonfuls every 4 hours.
Bismudin, 5.25%; 1 tablespoonful 3 times a day.
Citrace, 1.96%; ½ to 1 tablespoonful 3 times a day.
Glycerophosphates-Strychnine Compound, 5.1%; 1 to 2 teaspoons 3 times a day.

Gwia-Lyptus, 16.7%; 1 to 2 teaspoons every 3 hours.

Distinction should be made between the above products and any other by noting the percentage of the solvent contained, the doses of the preparation given, as well as differences in the character of the solvents.

A comprehensive toxicological study of the various glycols and their derivatives is in progress in our research laboratories. This work, as yet incomplete, indicates that the mono-ethyl ether ("Carbitol") is distinctly less toxic than diethylene glycol itself. A complete report of this research will be published in the near future.

Tests on the individual preparations named are being made. Gwia-Lyptus, which contains the highest percentage of "Carbitol," has been administered by stomach tube to white rats five times a day in doses of 2 cc. per kilo (equal on a weight basis to that contained in fifteen times the maximum adult therapeutic dose). At this high level of dosage the preparation has resulted in no deaths and has not prevented the continued growth and apparent normal development of the animals under continuous treatment for twenty days. One rat in this series which was sacrificed after sixteen days showed normal kidneys and liver.

STAINS FOR TRICHOMONAS VAGINALIS

To the Editor:—Will you kindly give me methods of fixing and staining smears which can be used for demonstrating *Trichomonas vaginalis*? Do the ordinary methods of staining show up the flagella? Does this organism have a sharp cell membrane? Could you also send me directions for preparing the various fixing and staining solutions?

M.D., New York.

ANSWER.—The usual procedure for studying flagellates is to stain them according to the Schaudinn fixation iron hematoxylin method. This requires considerable time and experience. It is almost impossible to complete the staining in less than twenty-four hours. Smears prepared by the Schaudinn method clearly demonstrate the protoplasm, nucleus and vacuolization, but the flagella are not always clearly visible. *Trichomonas vaginalis* can also be stained with the ordinary gram stain, but whereas the body structure of the organism is clearly demon-

strable the flagella are not often visible. Ewing and Le Moine (*Surg., Gynec. & Obst.* 48:192 [Feb.] 1934) experimented with many stains in an effort to bring out the flagella and finally found a dilute carbolfuchsin stain which invariably showed the trichomonas flagella and good body detail. The technic of making carbolfuchsin stains is simple and includes the following steps. (1) Smears are made thin; (2) they are fixed in air and not flamed; (3) the slides are covered with carbolfuchsin (about 20 to 25 drops); (4) 20 drops of distilled water is added and allowed to stand for three minutes; (5) the slides are washed with distilled water and dried between filter or blotting papers; (6) examination is made under an oil immersion lens. Ewing and Le Moine make two dry smears and a hanging drop in every case. One dry smear is stained by the usual Gram stain method and the other by carbolfuchsin.

A modification of Gram's method suggested by G. H. Ruhland and in use at the Mayo Clinic for many years is as follows:

1. Make smears, dry and fix by heat or mercury bichloride.
2. Cover preparation for half a minute with a 2 per cent solution of crystal violet in methyl alcohol of the highest purity.
3. Wash with water.
4. Apply Gram's iodine solution for one-half minute.
5. Wash in alcohol until purple ceases to come off. This is conveniently done in a watch-glass.
6. Apply a contrast stain for from one-half to one minute. A 1 per cent aqueous solution of safranin is much better than bismarck brown or fuchsin.
7. Wash in water, dry and mount.

The use of a hanging drop or wet smear under a cover glass occasionally offers difficulties when the trichomonads are few or when their motility is temporarily suspended. J. R. Miller (*THE JOURNAL*, Feb. 22, 1936, p. 616) found that a drop of 0.1 per cent safranin is useful as a diluent for the pus that is to be examined. Not only the nuclear material but the protoplasm also of the leukocytes rapidly takes the safranin stain, whereas the *Trichomonas vaginalis* organism remains unstained and conspicuous as a clear object against a slightly pink background. The safranin does not interfere with the motility of the trichomonads; if anything, it appears to stimulate it.

Trichomonas has a sharp cell membrane.

GASTRIC CRISES

To the Editor:—1. What factors precipitate attacks of gastric crisis in a patient subject to them? 2. Is there any prophylaxis against further attacks of gastric crisis in a patient who has already had several? 3. What percentage of patients with gastric crisis have a positive spinal fluid Wassermann reaction, an abnormal gold curve or an increased cell count, or an abnormal protein value at the time of the first attack?

M.D., New York.

ANSWER.—1. The factors that precipitate gastric crises in a tabetic patient subject to them are unknown. It has been suggested by various authors that the gastric crisis characterized by intense nausea and vomiting but without pain is vagal in origin, while that in which pain is the predominant feature, with nausea and vomiting subordinate or even absent, is due to involvement of the sympathetic system. These suggestions are, however, only hypotheses, since nothing definite is known of the pathology of gastric crises and the suggestions do not offer help in determining the precipitating factors. Actually the gastric crisis is distinguished from most other acute gastrointestinal upsets by the fact that it occurs in the absence of any precipitating factor.

2. The only prophylaxis against further attacks of gastric crises in a patient who has already had one attack is treatment of the underlying tabes or, if this fails, by further special measures directed at the gastric crisis itself. Routine antisiphilitic treatment is ineffectual. Subdural treatment with arsphenaminized serum by the Swift-Ellis method results in some relief from the gastric crises in about 25 per cent of patients treated. Fever therapy, preferably with malaria, will completely eliminate or definitely alleviate gastric crises in perhaps 50 per cent of the patients treated. If all of these methods fail, induced spinal anesthesia is occasionally successful. Numerous operations have been proposed for the relief of gastric crises, including chordotomy with section of the anterolateral columns, bilateral section of the vagus, posterior rhizotomy and abdominal sympathectomy. None of these operative procedures are particularly satisfactory and none should be attempted except as a last resort.

3. Approximately 20 to 25 per cent of tabetic patients with gastric crises may be expected to have normal spinal fluids or spinal fluids in which only minor abnormalities in cell count or protein content are present. In the remaining 75 to 80 per cent the several cerebrospinal fluid tests may be expected to be abnormal in varying degrees.

INTERMITTENT THERAPY OF SYPHILIS

To the Editor:—A man, aged 30, sexton and painter, married three months ago, acquired syphilis in October 1933 and first submitted to treatment during January 1934, at which time he had broken out with a secondary rash and ulcer in one tonsil. A roentgenogram of his chest showed old healed pulmonary tuberculosis in both apexes. Examination of the urine gave negative results. The Wassermann reaction was 3 plus with both antigens. He was given about sixty treatments each of neoarsphenamine and bismuth sodium tartrate during an eighteen months period, with rest periods after each six weeks of treatment of from one to two months. Most of the arsphenamine treatments were given earlier and the bismuth later in this period. Treatment was then stopped for several weeks because of the appearance of a positive albumin test. This varied from 1 to 2 plus and cleared up only to reappear on resumption of any of the usual metal treatments. I tried mapharsen 0.03 Gm., mercury rubs, "mixed treatment" tablets and potassium iodide in light doses and all provoked kidney irritation within a few days after their use. Even after one year's rest from all forms of treatment potassium iodide, 1 minim (0.06 cc.) three times a day, provoked irritation (as evidenced by a positive albumin test) within ten days. A recent Wassermann test was reported four plus with all antigens. A spinal tap has not been done. The patient feels well and there are no evidences of neurologic or vascular involvement.

M.D., New York.

ANSWER.—It is unfortunate that it is not clear whether the bismuth preparation was an aqueous solution or a suspension in oil. This would really make some difference. The aqueous preparation of bismuth sodium tartrate should be given three times a week to get a proper bismuth effect. The suspension in oil given once a week gives a reasonably good bismuth effect. This case shows well the mistake that is made in employing rest periods in the treatment of acute syphilis. After six weeks of treatment the patient was given from one to two months of rest. Is it not reasonable to suppose that the organisms remaining in the patient's body after a period of treatment would once more begin to multiply during this rest period? That probably explains why the patient still has a positive Wassermann reaction. The studies of the Cooperative Clinical Group have shown that relapses come early in the course of a case of syphilis and that they are far more prone to occur when the patient has been treated by the intermittent method of therapy. If continuous therapy is employed in the way of alternating courses of an arsenical and of a bismuth preparation, no opportunity is given for the spirochetes to multiply. The attack is a constant one, and the response of the disease to treatment is much better than when intermittent courses of treatment are employed.

The patient should be carefully examined from the standpoint of central nervous system syphilis and a lumbar puncture done at once. Moreover, the cardiovascular apparatus should be examined, for this type of patient is prone to cardiovascular, central nervous system and mucocutaneous types of relapse.

Until this information is at hand, it would be difficult to give more specific information as to what further should be done. If this patient had had the stated therapy given in a continuous manner without the rest periods, provided of course the bismuth preparation was a suspension preparation in oil, further therapy probably would not be necessary. As it stands, however, there is a question and further study of the patient is indicated.

DERMATITIS FROM BLACK CLOTHING

To the Editor:—A white woman, aged 34, has a dermatitis apparently caused by wearing black clothing. She states that during her entire life any time that she wears a black dress of any texture except pure silk the dermatitis appears within twenty-four hours on her neck, axilla and elbows; in other words, wherever the dress comes in contact with her skin. Is there any way that she can be desensitized to black dyes?

F. CECIL ADAMS, M.D., Klamath Falls, Ore.

ANSWER.—It is difficult to see why this woman is sensitive to black dyes in every other cloth but silk. As far as our information goes, black dyes in silk would not differ substantially from those used otherwise.

The subject should first test herself with a bit of material from a dress she wishes to purchase. The proper test medium is the patch method. A centimeter square or larger piece of test material is laid on a normal skin area, covered with an impervious material, such as waxed paper or oiled silk, and fastened into place with adhesive plaster. A positive test is indicated by an inflammatory response (often vesicular) of the skin directly in contact with the bit of cloth. The patch should remain in contact forty-eight hours and the results observed at that time and at intervals of a day. A positive test is manifested at times only after several days. Care should be exercised not to obtain a false positive test, as from the adhesive plaster used. At times only certain sites will react either with a clinical dermatitis or to a patch test. In such cases they must be the areas for testing to avoid a false negative result.

Rarely the axilla is such a special site, perhaps because the sweat differs from that of most of the rest of the skin.

Attempts to desensitize persons to dyes and other related materials has not had much success. The practical thing for the patient to do about her clothes problem is to wear only such garments as previously give her a negative patch test.

SPASMOSEDINE, CORTIODE AND EUTONON

To the Editor:—What would be an analogous American preparation to the following French Pill "Spasmosedine," which has the following formula:

Phenylethylmalonylurée	0.015	} Pour un comprime?
Bromhydrate de quinine	0.05	
Extrait de crataegus	0.05	

What is the physiologic effect of the French cortioid? What would be a fully effective American preparation having that effect? What is the German remedy "Eutonon," used with dextrose intravenously?

M.D., Chicago.

ANSWER.—The prescription translated would read as follows:

R Phenobarbital	0.15 Gm.
Quinine hydrobromide	0.50 Gm.
Extract of crataegus	0.50 Gm.

M. and div. into 10 caps.

One or two capsules two or three times daily might have a therapeutic effect in certain cases of precordial distress by acting as a sedative to cardiovascular innervation; phenobarbital has a tendency to lower blood pressure and quinine hydrobromide to slow the pulse rate. The value of crataegus is quite *sub judice*. Its effect, if any, as a sedative to the circulation is quite irregular and often so slow in asserting itself that its real value has been doubted. The following prescription yields a sedative effect on the circulation for the relief of precordial distress by a depressant action on various portions of the nervous system:

R Phenobarbital	0.5 Gm.
Quinine hydrobromide	2.0 Gm.
Carbromal	4.0 Gm.

M. and div. into 15 caps. One three times daily after meals.

"Cortioid" is stated to contain "iodobenzomethyl monoforimine," a substance formed by the combination of iodine (42 per cent) with formaldehyde and a benzyl radical. It is probable that the better known sodium iodide is entirely equivalent in therapeutic effect in arterial hypertension, angina pectoris and coronary sclerosis whether given by intravenous injection or by mouth.

"Eutonon" is a liver extract, said to contain tyramine and choline as its active principles; it was originally proposed for use as a depressor substance but results have been disappointing.

LIPOID HISTIOCYTOSIS, OR NIEMANN-PICK'S DISEASE

To the Editor:—A baby, aged 8 months, had frequent spells of vomiting since five months following delivery. About four months ago the liver and spleen became enlarged and have continued to increase in size. The blood count showed hemoglobin 75 per cent, red blood cells 4,560,000, white blood cells 10,600 and a normal differential. About two weeks ago, bone marrow studies were made in the hospital. Vacuolated white blood cells were found in the blood smear and "foam" cells were found in the bone marrow smears. A variation in the normal macula of the eye was found, but this was not a typical cherry red spot. Diagnosis of Niemann-Pick's disease was made. What is the present status of opinion regarding etiology and treatment?

M.D., New York.

ANSWER.—Niemann-Pick's disease, or lipid histiocytosis, is a disturbance in lipid metabolism of unknown etiology which is characterized by a widespread deposition of lipid material, essentially phosphatids, in large foam cells in all the organs of the body, particularly the spleen, liver, bone marrow and lymph nodes. The disease is congenital and familial and occurs almost exclusively in infants of the Jewish race. It runs a rapid downhill course and is always fatal. There is no known treatment at present that is of any value.

Niemann-Pick's disease must be differentiated from the other xanthomatoses, such as Gaucher's and Schüller-Christian's disease. The blood lipids are usually increased to from two to four times the normal amount. A cherry red spot in the retina may be present, suggesting a relationship to amaurotic family idiocy, in which the lipid disturbance affects only the central nervous system. The most valuable diagnostic procedure is sternal aspiration, which reveals the characteristic foam cells in the marrow.

The cause of the abnormal lipid metabolism in this disease is unknown. The most plausible theory, as suggested by Pick, is that of Sobotka and his associates. These investigators believe that the disturbance lies in the inability of the normal fat-forming cells to convert lecithin-fatty acid esters into neutral

fat. They suggest that certain enzymes which are present normally and which are necessary for this process are lacking in this disease. This theory is still unconfirmed.

POSSIBLE POSTENCEPHALITIC SYNDROME IN GIRL

To the Editor:—A girl, aged 13 years, in good health until she was 8½ years of age, was seized suddenly one morning at about 6 o'clock with an attack of loud, labored breathing, associated with a spasm of the entire body and unconsciousness which lasted about forty-five minutes. A month later a similar attack occurred, and gradually these attacks have increased in frequency until at present the patient has from fifteen to sixteen every twenty-four hours. The attacks last about two minutes now. They come on suddenly, without an aura, and have the following characteristics: At the onset both eyes turn upward and the child falls backward to the floor with both eyes turning to the left, the child turning the entire body counterclockwise. The body is rigid and there is no clonus. The patient loses consciousness during an attack and only recently has she had involuntary urination during the attack—although never an involuntary bowel movement. Following the attack the child breathes heavily, is very weak and makes purposeless movements such as pulling her fingers, scratching her head and picking her nose. The only other essential point in the history is that about one year previous to the first attack the patient complained of an almost constant generalized abdominal aching with frontal and parietal headaches, at which time the mother thought the child had worms. At present the child has a blank expression, answers questions infrequently and obviously is mentally deficient. Her speech is somewhat slurred and monotonous. There are no definite cerebellar signs and the reflexes are all normal. The past history revealed frequent sore throats during childhood, and about three months before her first attack a tonsillectomy and adenoidectomy was done. Her first menstrual period was in March 1937 and the next was in June, and since then she has not menstruated. The physical examination, urine and blood examination are essentially negative. Please advise as to possible diagnosis or suggestions for work-up. M.D., Illinois.

ANSWER:—The history of paroxysmal attacks of forced breathing associated with convulsive manifestations suggests the possibility that one is dealing with a postencephalitic syndrome. The upward turning of the eyes and the loss of facial expression are compatible with this possibility.

An encephalogram would be valuable from both a diagnostic and a therapeutic point of view. One would rather expect to find some cortical atrophy, as well as enlarged ventricles. This procedure also provides for skull roentgenograms and spinal fluid examination. If encephalitic in character, the sugar content of spinal fluid may be elevated.

The following therapeutic tests are valuable:

1. Scopolamine hydrobromide 0.00065 Gm. (1/100 grain) three times a day.
 2. Tincture of stramonium in graduated doses of from 0.6 to 3 cc. three times a day.
 3. Atropine sulfate in graduated doses of from 0.00026 to 0.0013 Gm. (1/250 to 1/100 grain) four times a day.
- This must be graduated slowly under careful observation, about three weeks being allowed to reach the maximum doses. In encephalitic syndromes, definite amelioration may be obtained.

MARBLE BONE DISEASE

To the Editor:—A patient, 19 months old, has been diagnosed as having marble bone disease (Albers-Schönberg disease). What is the etiology and treatment? What is the prognosis? Ph.G., New York.

ANSWER:—The etiologic factors producing marble bones (Albers-Schönberg disease) are not known. Occurrence of the disease in more than one child in the same family, in a child and one parent, and in cousins suggests a familial tendency. Kinship between the two parents of many of the patients has been reported, and this has led to the theory that inbreeding may be a factor in producing the disease. An abnormally high inorganic phosphate content of the blood has been reported in these patients, while the blood calcium content has been normal. The patients show marked calcium and phosphorus retention or a high positive mineral balance. A condition quite similar to this can be produced in rats by repeated injections of parathyroid extract. The abnormal mineral metabolism in patients suffering from marble bones definitely suggests that the primary etiologic factor is caused by disturbance in the endocrine glands, and the parathyroid glands are most under suspicion.

No treatment has been of definite benefit. McCune and Bradley (*Am. J. Dis. Child.* 46:1462 [Dec.] 1933) treated a patient with this disease by administering parathyroid extract but were not successful either in obtaining a negative calcium or phosphorus balance or in changing the appearance of the marble bones. Surgical removal of one or more parathyroid

glands has been suggested. The danger of death from tetan and the incomplete information regarding the disease would seem to cast much doubt on the justification for this operation.

If the condition is generalized, with involvement of the bone of the skull and face, the prognosis is poor. The nerve foramina may become encroached on, this condition resulting in blindness deafness or both. The sclerosed bones are brittle and fracture are common when the long bones are involved. Such fracture heal with excessive amounts of callus.

The infants often die from inanition or intercurrent infection. In mild cases with relatively little involvement of the bones of the skull the patient may live a normal life, marry and have children. Pirie (*Am. J. Roentgenol.* 24:147 [Aug.] 1930) has reported Albers-Schönberg disease in a patient aged 58 years.

TREATMENT OF OBESITY

To the Editor:—A woman, aged 25, who has been increasing in weight for a number of years, was treated with radium for metrorrhagia. She seems to think that her weight increased more rapidly after that. The basal metabolic rate taken some time ago was said to be low. Her hips, thighs and abdomen are so conspicuously large that her husband will not be seen out with her. Enteric coated tablets of thyroid 5 grains (0.3 Gm.) taken two or three times a day do nothing more than accelerate her pulse and cause dyspnea on the least exertion. Dinitrophenol 1½ grains (0.1 Gm.) three times a day after eating does nothing more than increase her weight. A combination of two dinitrophenol capsules a day and one thyroid tablet has no effect. Double strength solution of posterior pituitary 1 cc. or more administered by the patient every day for three weeks has resulted in a gain of 6 pounds (2.7 Kg.). The only good she has obtained from it is more clearness of cerebration and greatly increased energy for housework. She administers the solution of posterior pituitary in the same manner in which a diabetic patient administers insulin, except that a slightly longer needle is used so that the injection is made into the quadriceps. Antuitrin and antuitrin-S have reestablished the menstrual periods to a certain extent but without any effect on the weight. A physician once prescribed a diet of skimmed milk and spinach for her and after three weeks she had gained considerably. Is there anything about the pancreas that might affect the deposition of fat or rather increase its deposition independent of the pituitary gland? It is evident that there are mysteries which still shroud such cases of obesity as this; however, your opinion in the matter of the underlying pathologic condition and its possible treatment would be greatly appreciated. M.D., Mass.

ANSWER:—Although there are many mysteries concerning such cases, they will never be solved by indiscriminate use of substances that are without a sound therapeutic basis. This patient was given 0.3 Gm. of thyroid in spite of the fact that the only recorded knowledge of her basal metabolism was that it "was said to be low." If the patient's basal metabolic rate is known to be low, it should be raised by means of scientific administration of definite amounts of a standard brand of thyroid and frequent determinations of the basal metabolic rate should be made in order to keep the rate somewhere between minus 10 and zero. Another type of therapy mentioned is the use of capsules of dinitrophenol. It should be apparent to every one that this type of therapy should be abandoned. The risk of toxic effects, particularly the formation of cataract, is too great to warrant the use of such a dangerous drug. Another type of therapy mentioned is the use of solution of posterior pituitary. There is absolutely no basis for use of this substance in this case. Use of antuitrin and antuitrin-S is also open to question.

There is only one good way of approaching simple obesity and that is by means of diet. A well planned regimen for reduction of weight, such as has been outlined by Strang and Evans (*Treatment of Obesity with Low Caloric Diet, THE JOURNAL*, Oct. 10, 1931, p. 1063) should be tried. Regardless of the fundamental cause of obesity in different cases, the fact remains that food is the only source of fat and that the only way to prevent the deposition of fat is by restricting the patient's caloric intake. Failure following the use of a rigid regimen for reduction of weight is virtually unheard of and certainly this is the first and most important procedure to be tried in the case described.

IDE TEST FOR SYPHILIS

To the Editor:—What is your opinion on the value of the Ide test for syphilis as compared with the Wassermann test? Where can the necessary antigen be obtained? M.D., New York.

ANSWER:—Sobei Ide and Tamao Ide of Tokyo, Japan, reported on their test in the *Journal of Laboratory and Clinical Medicine* (21:1190 [Aug.] 1936) and also in the *Klinische Wochenschrift* (15:973 [July 4] 1936). Since that time little has appeared in the English literature. An article appeared in the *Philippine Islands Medical Association Journal* (16:609 [Oct.] 1935) by Quisumbing. This was abstracted in *THE JOURNAL* Jan. 30, 1937, page 428. Another article appeared in the *Bulletin de la*

Société française de dermatologie et de syphiligraphie in December 1937, page 2101, abstracted in *THE JOURNAL* March 26, 1938, page 1067, by Demanche and Ségall, who employed Ide's test on 295 subjects, 226 of whom had treated or untreated syphilis in different stages. Results were compared with the Wassermann, Kahn and Meinicke tests. They concluded that the Ide test is less scientific than the other tests and less accurate because of difficulty in reading. Great caution in the use of the newer tests for syphilis has also been stressed in a recent current comment in *THE JOURNAL* 110:1373 (April 23) 1938. For the present, therefore, the test cannot be considered as a substitute for the standard methods and if used must always be controlled by other recognized laboratory procedures.

PRIMARY SYPHILIS AND MARRIAGE

To the Editor:—Over a year ago a patient presented himself with a lesion on the penis which was diagnosed by dark field examination as a primary syphilitic lesion. Treatment was immediately instituted along the plan suggested by the Cooperative Clinical Group of the United States Public Health Service, Stokes, Schamberg, Cole and others. The arsenicals and bismuth compounds were given in alternating courses as well as in combination, and the patient was advised to stay under treatment for at least seventy weeks or a year and a half as advised by the committee. What assurance can I give this patient at the end of the seventy weeks as to the certainty of his being cured? His serologic reaction was never positive. Would the indulgence in alcoholic beverages interfere with or retard the efficiency of the treatment? If there is a negative reaction after one year from the time treatment is finished, would it be advisable for him to consider marriage, and if so when could marriage be considered?
M.D., Pennsylvania.

ANSWER:—The chances of the patient's being cured are very good if his serologic reaction has never been positive. In other words, the patient has had a case of seronegative primary syphilis. It is felt that the use of alcoholic beverages interferes with the efficiency of antisymphilitic therapy.

At the end of one year it is advised that a lumbar puncture be done, and a Wassermann test should be taken every two months. If the tests have all remained negative for one year after all therapy has been discontinued, the test may be taken every six months for the succeeding year. At the end of the second year there should be a thorough physical examination, including a careful check on the cardiovascular apparatus.

Three and one-half years after he contracted syphilis, it would probably be safe for him to marry. He should consult his physician for a general physical examination once a year, however, as well as for a serologic check-up. This means that the patient should wait for two years after the stopping of treatment before considering marriage. The marriage would be dependent on a negative physical examination, a negative lumbar puncture and a negative check-up of the cardiovascular apparatus.

ABDOMINAL PAIN FROM EXERCISE AND APPENDICITIS

To the Editor:—As public school physician I have to pass on all excuses from physical education, in high school, and frequently get a story from the girls as follows: They complain of pain in the right lower quadrant after running and say they want to be excused because of appendicitis. Frequently they have been told by their family physicians that they have a chronic appendicitis. Examination of such cases is always negative. I should like to know the mechanism of pain in the abdomen following exercise. We all have "catches" after running when not in training. Can this type of pain arise from an appendix or is it muscular? My feeling has been not to pay too great attention to this as an excuse from the ordinary gym class. Am I thus causing some child to have an attack of appendicitis?

R. NED WHITE, M.D., Springfield, Mo.

ANSWER:—The occurrence of abdominal pain following exercise is common but the explanation of this phenomenon is not easy. Dr. J. L. Capps, in his book on pain, says that "the external surface of the body can be stimulated at will by painful stimuli and the location of the pain so induced can be readily determined. But within the cavities of the body a given stimulus may produce no sensation whatever in the region of the stimulus or it may give rise to painful sensations at a distant point."

Because of the fact that nearly all persons who complain of this type of pain are perfectly healthy, no underlying organic pathologic condition is involved in its production. Exactly what does produce the pain is at present a matter of speculation and inductive reasoning. It has been charged to distention of the splenic and hepatic capsules, anoxemia of the intestinal muscles, anoxemia or spasm of the diaphragmatic muscle, and other causes. It is likely that some or even all of these causes may be correct but experimental proof is lacking at the present time.

Such pain is not produced by chronic appendicitis or by other organic disease. Appendicitis may exist in a person who

has such pain but a diagnosis cannot be made on the occurrence of pain following exercise. There must be other evidence.

While there may be controversy about the direct cause of appendicitis, there is no evidence to show that exercise produces it.

TINCTURE OF IODINE AND MILK

To the Editor:—I have been informed that raw milk may be rendered as safe for human consumption as if pasteurized by the addition of nine drops of tincture of iodine to each quart, the mixture being allowed to stand for six hours. This idea has been refuted also by a good authority. Will you be good enough to inform me whether there is any scientific basis for this procedure?
HAROLD J. HARRIS, M.D., New York.

ANSWER:—Four one quart samples of certified raw milk, which had previously been treated to a sediment test, were plated to determine the bacterial count.

Each bottle was then treated with nine drops of tincture of iodine (44 parts per million of free iodine), allowed to stand six hours, and the samples were again plated. The results are given in the table.

Results of Test

Sample Number	Bacteria per Cubic Centimeter		Place of Storage During Six Hour Period
	Untreated Sample	Sample Treated with Tincture of Iodine	
1	36,000	47,000	Icebox, 8 C.
2	33,000	71,000	Icebox, 8 C.
3	390,000	250,000	Icebox, 8 C.
4	310,000	420,000	On table in laboratory, 22 C.

These results show that the addition of nine drops of tincture of iodine to a quart of milk has little or no inhibiting effect on the growth of bacteria in milk after six hours.

PULSE PRESSURE

To the Editor:—Please explain the following sphygmomanometric paradox: In a man aged 45, with no apparent circulatory abnormality, the first sound over the brachial artery was heard at 175 mm. of mercury, at which point the column also regularly began oscillations. This low pitched sound continued to be heard until the mercury registered 110 mm., at which point the sound was greatly intensified and the pulse at the wrist was felt for the first time. Sounds completely disappeared at 50 mm. What should be considered the systolic pressure? I can usually feel the radial pulse a little below the point of beginning oscillation and stethoscopic first sound, but how can the gap of 65 mm. be explained?

M.D., New Jersey.

ANSWER:—Probably the low pitched sound heard during the compression interval from 175 down to 110 mm. was the result simply of a forceful pulse thudding against the closed artery under the cuff. This occurs not infrequently, especially if the arm is thin and the pulse strong. Rarely the difficulty arises as a definite source of confusion. It can be obviated by the use of a double cuff or by two cuffs, one above the other, with auscultation just below the lower cuff.

It is much less likely that this is an instance of true auscultatory gap. When there is an auscultatory gap the sounds are clearly heard above the gap, at least for a few millimeters, and then there is a dulling or entire absence of the sounds for 30 or 40 millimeters with a return of the sounds below this level. Such a gap is rare except in essential hypertension or aortic stenosis.

ACACIA IN HEMORRHAGE AND SHOCK

To the Editor:—Of what value is acacia solution in hemorrhage and shock, the acacia solution being the standardized 6 per cent solution in dextrose, in a total quantity of 500 cc. How much time should be consumed in the administration of such a quantity? In cases coming to necropsy in which acacia solution has been used, what is the gross and microscopic appearance of the liver?
M.D., Illinois.

ANSWER:—Acacia solution is of great value in the treatment of severe hemorrhage and shock and should always be available at short notice. It is remarkable to observe the rapid improvement of the patient who is practically pulseless and has a low pressure with the intravenous administration of acacia solution. Acacia solution with sodium chloride is preferred. The standard commercial ampule is 100 cc. and contains 30 Gm. of acacia and 4.5 Gm. of sodium chloride. Four hundred cc. of freshly distilled sterile water is added to this solution, so that for the final dilution of 500 cc. each hundred cubic centimeters contains 6 Gm. of acacia and 0.9 Gm. of sodium chloride. In an exsanguinated patient, when blood is not immediately available, this solution may be given rapidly. One thousand cc. of acacia solution in from thirty to sixty minutes is not too fast in the desperate case.

The liver, as part of the reticulo-endothelial system, plays a part in the elimination of the acacia. A competent pathologist, with whom this subject has been discussed, has observed no gross or microscopic changes in the liver after the use of acacia, although this question has not been finally settled. For days or weeks after the administration of acacia, the microscopic appearance of the blood is so altered that a leukocyte count is difficult or may be impossible.

THRESHING FEVER, OR WHEAT MILLER'S ASTHMA

To the Editor:—In my rural practice, during the threshing season, I encounter a condition commonly called "threshing fever." It is characterized by a more or less sudden onset, malaise, severe headache, high fever—from 102 to 105 F.—chest pains, accompanied by a constricted feeling across the chest, short and rapid respirations accompanied by an irritating cough, scanty expectoration, at times blood tinged, and a pulse rate of from 90 to 110. The course of the disease is short, the patient usually recovering in a period of from seven to ten days with no apparent after-effects. The treatment has been symptomatic. The condition seems to be that of an acute pneumonitis due to the inhalation of the dust particles incidental to threshing. I have been unable to find any reference to this condition in the literature.

M.D., Pennsylvania.

ANSWER.—In the literature the condition described as "threshing fever" is referred to as wheat millers' asthma or as grain threshing bronchial catarrh. Several theories concerning its etiology can be advanced. It has been elaborately described by W. W. Duke in two articles (*J. Allergy* 6:568 [Nov.] 1934; *THE JOURNAL*, Sept. 21, 1935, p. 957). He attributes the condition to irritation from the serrated hairs found in the wheat dust.

Other theories are presented in Kober and Hayhurst's *Industrial Health* (Philadelphia, P. Blakiston's Son & Co., 1924, p. 214). Kober attributed the condition either to intoxication from the grain protein or a contained fungus or to irritation from inorganic dust present in the grain. The possibility of a pyococcic bronchitis on an allergic respiratory response must be considered.

RADIOSENSITIVE AND RADIORESISTANT TUMORS

To the Editor:—A man, aged 48, has a growth on the side of the nose about the size of a grain of corn. The pathologic report by competent pathologists was adenocarcinoma, radiosensitive, type 2. Radium was applied. Two and one-half months later there was some evidence of a malignant growth being present. The entire area was resected again and sent to the same pathologist. This time he reported it to be basal cell epithelioma, radioresistant. Will you advise whether an adenocarcinoma, radiosensitive, type 2, will change to basal cell epithelioma, radioresistant, within two and one-half months and what part the radium would play in this change?

M.D., Georgia.

ANSWER.—The problem of grading tumors in relation to radiosensitivity and radioresistance is an extremely difficult one and by no means settled. The morphologic changes in a tumor that are caused by radiation are also difficult to interpret, even by those with great experience in this field. In the particular example cited, the answer is in the negative.

There are two factors which have to be considered: One is the fact that the pathologist had an opportunity to examine the entire specimen the second time, as compared with the examination of only a limited portion of it in the beginning. The second factor is the change produced in the tissues by irradiation.

OPERATION FOR STERILITY IN MALE

To the Editor:—A man, aged 46, was sterilized about eight years ago by ligation of the vas deferens, and a small piece of the vas was removed between the points of ligation. He now is married again and wishes to have the sterilization corrected in order to become the father of a child or two. What type of operation is advisable to establish continuity of the vas deferens, and what are the chances that it will be successful? The man is normal otherwise and there is no history of epididymitis or orchitis.

M.D., Minnesota.

ANSWER.—While it is possible to unite the two ends of the vasa, the most sensible operation would be that of epididymo-vasostomy just as for occlusion after an epididymitis. The operation proposed by Hagner, a description of which can be found in any book or article dealing with sterility in the male, has been the most successful. Whichever method is employed, it is essential at the operation to test the patency of the vasa, and it would be advisable beforehand to aspirate the testicle to see if it produces spermatozoa. The prognosis is poor no matter what procedure is employed and only about 30 per cent of operations are successful when judged by finding five spermatozoa in a condom specimen after the operation. The operation itself is not dangerous and, if properly done, can do no harm even if unsuccessful. Occasionally it may be repeated later on.

GAS HEATERS

To the Editor:—Might heating with unventilated radiant heaters supplied with natural gas be considered unhealthy and, if so, why?

L. L. HILL JR., M.D., Montgomery, Ala.

ANSWER.—Tens of thousands of the radiant type of gas heaters are in use throughout the country without attracting special attention as creating injurious exposures. The use of natural gas is preferable to artificial gas, since the former usually contains little or no carbon monoxide. Under fortuitous circumstances any gas heater, through defects, may become dangerous and carbon monoxide gas may be produced through improper combustion, and disaster may rise. Natural gas, while ordinarily nontoxic, is a simple asphyxiant and may replace ordinary atmospheric oxygen to the point at which life will not be supported. If turned-on gas in a radiant heater is unlighted, if the flame is blown out or it is otherwise discharged in any confined space, such as a room, a potential exposure naturally exists. A vented heater is desirable and when they function properly the prospects of injury are low.

PEDICULOSIS AND ETHYL ACETATE

To the Editor:—Please supply information on the use of ethyl acetate in the treatment of pediculosis capitis.

R. N. MONFORT, M.D., Onaway, Mich.

ANSWER.—No mention of ethyl acetate in the treatment of pediculosis capitis has been found in the medical literature of the last few years. If such mention has been made, it may be hidden so that search of the index does not reveal it.

Ethyl acetate, acetic ether, or vinegar naphtha is a volatile liquid of fruity odor which causes a temporary burning sensation when applied to the skin and some dryness of the skin thereafter. The fact that it is inflammable is an objection to its use undiluted. The method of treatment in favor at present is the application of a thick layer of petrolatum containing 5 per cent benzene in the effort to smother the lice. After this has been accomplished the petrolatum is removed, the scalp washed and a dressing of hot vinegar applied for a time to loosen the nits, which can then be removed with a fine comb. It is possible that acetic ether suitably diluted would accomplish these objects more easily.

COITUS DURING PREGNANCY

To the Editor:—There is an underlying current of thought that would substantiate the idea that sexual intercourse during pregnancy is detrimental to the child to be and that it may cause idiotic conditions. Is this true? If, so, through what means? If these are incorrect ideas, what is the reason for some believing them to be so? M.D., California.

ANSWER.—There are no facts to substantiate the idea that sexual intercourse during pregnancy is detrimental to the child or that it may be responsible for idiotic conditions. There are a few ancient superstitions on this score which have proved to be groundless.

TERMINOLOGY OF HUMAN AND DOG TAPEWORMS

To the Editor:—A student maintains that *Diphyllobothrium latum* and *Diphyllobothrium latus* are one and the same parasite, while I contend that they are two distinct species, one, *Diphyllobothrium latum* being the fish tapeworm infesting man and the other being the fish tapeworm infesting dogs. For a long time it was common to consider the two as identical. However, I am quite sure that the most recent work has shown the two to be distinct. Your answer and any references that you can give me on the subject will be welcomed.

M.D., Minnesota.

ANSWER.—*Latus* and *latum* are respectively the masculine and neuter Latin forms of the specific name of the broad or fish tapeworm of man. The fish tapeworm of the dog and cat has generally been called *Diphyllobothrium mansoni* (Cobbold) but recently Neveu-Lemaire in his *Traité d'helminthologie* revived an older name, *Diphyllobothrium erinacei* (Rudolphi) for it.

PATRICK'S SOLUTION FOR NERVE INJECTION

To the Editor:—Can you furnish the formula for Patrick's solution, which is an alcohol solution for injecting nerves?

W. T. THORNTON, M.D., Missoula, Mont.

ANSWER.—The formula given by Patrick in *THE JOURNAL*, Jan. 20, 1912, page 155, is:

	Gm. or Cc.	gr. ii
Cocaine muriate	11	5 iiiss
Alcohol	13½	5 ss
Aqua destillata, q. s.	15½	

This solution is intended only for injection of the trigeminal nerve and should not be used for mixed or motor nerves unless it is intended to cause paralysis.

Book Notices

The Principles and Practice of Clinical Psychiatry. By Morris Braude, M.D., Associate Clinical Professor of Psychiatry, Rush Medical College, The University of Chicago. Cloth. Price, \$4. Pp. 382, with 7 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1937.

Book after book has been written for the student of psychiatry. Most of them are thoroughly similar, thoroughly accurate and, for the most part, well written. It is somewhat difficult to see, perhaps, exactly what this book can accomplish which previous works on psychiatry have not done. One favorable feature, however, which might be pointed out is the fact that the dynamics of the various mental diseases are more largely dwelt on than the merely descriptive features. For instance, in the discussion of dementia praecox much space is devoted to an attempt to explain why one type might be so apathetic and why the symptoms take the form that they do. For adopting this rather novel point of view the author deserves praise.

The book begins with an excellent introduction, after which each one of the usual psychiatric entities, such as manic-depressive psychosis, dementia praecox and organic and toxic psychoses are taken up in detail. The conventional presentation is largely adhered to in that the definitions, the etiology, the symptomatology and the differential diagnosis are simply and competently summarized. A page or two is devoted to each of the more rare conditions, such as lead encephalopathy, and not much fault can be found with the actual material presented. There are a number of excellent case histories, which in many instances present the symptomatology and behavior of the case better than the descriptions included in larger, older and more detailed textbooks. For a small summary of psychiatry brought down to date and incorporating dynamic thinking, the volume would fill the bill. Little criticism can be made of the style. There is a short bibliography as each chapter ends, and brief chapters on simulation or malingering, mental deficiency and psychoanalysis conclude the book. The chapter on neuroses and psychoneurosis, which was usually so weak in earlier textbooks, is not much better in this volume. It is an excellent handbook and there seems to be little in it that would prevent it from serving as an elementary textbook for medical students of psychiatry.

Apoplexies viscérales séreuses et hémorragiques (Infarctus viscéraux). Par Raymond Grégoire, professeur à la Faculté de médecine de Paris, et Roger Couvelaire, chirurgien des hôpitaux de Paris. Paper. Price, 50 francs. Pp. 181. Paris: Masson & Cie, 1937.

The authors made an exhaustive study of visceral infarcts (apoplexies) from the clinical point of view. They point out that misinterpretation of symptoms the result of visceral infarctions frequently result in tragedies and loss of life. The clinical entities under discussion tax the diagnostic acumen of both physician and surgeon. The authors' ingenious experiments on lower animals in their approach to a possible solution of the problems presented yielded some interesting conclusions. First, the authors produced anaphylactic shock by artificial means on laboratory animals. From these they were able to conclude that experimentally produced anaphylactic and anaphylactoid shock is followed, essentially, by the same results observed in disturbances of the vegetative nervous system occurring in human beings under similar conditions. Careful comparisons are drawn of the results obtained from animal experimentation with those of clinical patients. While the authors do not claim that their conclusions are final or incontrovertible, their deductions seem logical. For example, apoplexies observed within the abdomen of human beings bear a striking resemblance in symptomatology to the apoplexies artificially produced in laboratory animals. The authors point out that hemorrhagic pancreatitis, intestinal infarcts and tubo-ovarian apoplexies manifest themselves at the onset by symptoms of shock, lipothymia and a decided fall in the blood pressure. These phenomena are accompanied by venous distention. These the authors attribute to "shock of intolerance." Similar manifestations were noted in the animals experimented on. The question the authors ask is: Are visceral apoplexies the result of primary alterations in the vegetative nervous system which react in an

abnormal manner on the vascular apparatus? If that is so, a new chapter is opened in pathology. The therapeutic indications garnered from a study of the symptoms produced by serous and hemorrhagic apoplexies of the intestine the result of experimental and clinical data are given. Supposing the surgeon in charge of a case is an experienced technician, the problem reduces itself to the question as to What procedure is best in the interest of the patient? If, as the authors believe, such apoplexies are the manifestations of "shock of intolerance," one must determine how much damage the existing neuro-vegetative disorientation has produced on the particular viscera affected. Two urgent indications are postulated: First, the treatment of the shock syndrome per se. Second, immediate verification of the degree of alteration produced in the structure of the intestine. The authors point out that the symptom complexes under consideration may disappear spontaneously. The keynote of procedure is to combat low blood pressure, the result of shock, by sodium thiosulfate or epinephrine. Case histories cited show how spontaneous recoveries may take place in the form of infarction. It is pointed out that the use of general anesthesia by itself may be a curative factor by suppressing nervous impulses. Clinical histories support the thesis presented. The reader will find chapter 4, on serous and hemorrhagic apoplexies of the pancreas, when read in conjunction with chapter 5, on serous and hemorrhagic apoplexy of the lung and chapter 6, dealing with serous and hemorrhagic apoplexy of the uterus, interesting and illuminating. The work is completed by a discussion of spontaneous serous and hemorrhagic apoplexy from the clinical and anatomic points of view. For the advanced student as well as for the diagnostician and surgeon, the work is highly recommended for its intrinsic value as a classic contribution to the physiopathology and treatment of these rather common and obscure clinical entities.

The Patient and the Weather. By William F. Petersen, M.D. With the assistance of Margaret E. Milliken, S.M. Volume IV, Part 2: Organic Disease. Hypo and Hyperthyroidism, Diabetes, The Blood Dyscrasias, Tuberculosis. Cloth. Price, \$11. Pp. 729, with 380 illustrations. Ann Arbor, Michigan: Edwards Brothers, Inc., 1937.

In spite of the fact that several other large volumes have already appeared in this series, in this volume Dr. Petersen begins to approach the conditions which are much more to the interest of the general medical man than were those discussed in previous volumes. While it is true that heart disease has been touched on previously, the present tome deals with tuberculosis and with a number of other disorders which arise more often in the experience of the general practitioner and internist than do the mental diseases and other conditions to which were devoted much of the space in the preceding volumes. Dr. Petersen is interested in correlating the general trend of climatic change with disease. Fluctuation in temperature, humidity, pressure and other weather changes are correlated day by day with many bodily variations due to disease. The reason Dr. Petersen thinks these might be of importance is that he is of the opinion that changes in pressure in the capillary bed definitely occur with changes in the weather. This he has demonstrated to some extent in previous volumes, and while perhaps the results are not absolutely conclusive, they are definitely indicative of a relationship which should be thoroughly studied. The present volume is perhaps no more convincing or strictly practical than the preceding volumes. Its organization is not quite as systematic as the first part of the present volume, (volume IV, part 1), so that in the part now being reviewed one finds discussions of the cretin, the hyperthyroid and the thyrotoxic cases, followed by a mention of mortality rates, beginning with exophthalmic goiter and carrying over into postoperative tetany and into racial distribution of goiter. Perhaps in a broad sense all these have a bearing on the problem and as one reads through the volume, not an easy task, one is able to understand why the author has run these conditions together, even though, discretely, the titles may not seem to be closely interrelated. The reason, apparently, is that they all depend on endocrinologic functions, which in turn determine and depend on changes in the blood vessel capacity. With these changes in blood vessel capacity, due to the weather, the author attempts to show that there are acute exacerbations of symptoms or diminution. This seems particularly to be true

in diabetes. Changes in blood sugar in several cases which the author presents correlate quite highly in the individual case with changes in climatic conditions.

In the present volume, as in those previously published, there are numerous case histories, some given in considerable detail, others summarized rather briefly. In most of them are complex charts giving the changes in the various bodily functions as they are measured in the hospital, showing at the same time the various meteorological changes which were recorded for the same date. The charts of most of the exacerbations and clinical changes do not superimpose exactly on the main features of the weather brought out by Petersen, yet there is a close enough relationship in these cases of thyroid disease and pancreatic disease to say that in these disorders the point is as well made as it has been in the nervous, mental and other conditions which were analyzed in previous volumes. The blood dyscrasias too are presented in some detail, but the case material here does not seem to be as strongly demonstrative of inter-relationship between the symptomatic change and the weather. A third part of the book is devoted to a discussion of the relation of the weather to tuberculosis. A gross relationship of weather to pulmonary conditions, of course, has been admitted for generations, although some doubt has from time to time been cast on definite statements as to the exact nature of the relationship. Most of the studies in the past have tended to show that changes in climate continuing over periods of time have an effect, good or bad, on pulmonary tuberculosis. Petersen shows that unitary climatic changes have an effect.

There does not seem to be much of a practical nature brought out in the book, the author's thesis being purely one of research based on the hypothesis that symptomatic conduct is predicated on environmental changes such as those occurring in the weather. There are a number of splendid illustrations of pathologic material to illustrate the many case histories, and the bibliography at the end of each discussion of a group of pathologic entities is excellently gathered and shows wide reading and study. This volume, like the others, is not one which would add much to the armamentarium of the physician who must treat his patients immediately. For the specialist in endocrine function, in the blood dyscrasias or in tuberculosis, there would seem to be a need for reading the part of this book devoted to his specialty to give him Petersen's point of view and possibly to stimulate him to further thought in this interesting field.

Emotional Adjustment in Marriage. By Le Mon Clark, M.S., M.D., Assistant in Obstetrics and Gynecology, University of Illinois College of Medicine. Cloth. Price, \$3. Pp. 261. St. Louis: C. V. Mosby Company, 1937.

With the rapid clinical development of marriage therapy, a book on emotional adjustment in marriage has long been awaited. There is no doubt that marriage is one of the most important problems that confront the human race today. Even the actual excuse for its existence is under fire. Clinicians are anxiously attempting to analyze the social factors which make for good marriage, conditions that have been statistically studied by Dickinson, Hamilton and others for the purpose of finding out attitudes, interests and sources of conflict in marriage, and the psychiatrist has gone into considerable detail to understand where the dynamisms possible for success and failure in this relationship are built up. The gynecologist has a place in marital adjustment. Practically speaking, he is probably called on more often to advise mismatched couples than any other professional individual. His knowledge of the generative organs of the female, which after all offer more chances for pathologic change than do those of the male, often makes him able to give some advice which will enable a couple seemingly mismatched to make a readjustment. One would hope from the title that Clark would develop a volume beyond mere mechanics, but one is doomed to disappointment. The chapters are, of course, devoted to a discussion of normal sex adjustment, to the concepts of morality, and advice is given as to the conduct of the honeymoon and the period after the honeymoon. But Clark's vision is limited. He probably has no concept of the various fears, abnormal attachments, social obligations and adjustment mechanisms which occur in even the most apparently normal lives. This book is largely conventional. Much of it apparently is culled from literature in the anthropologic

field or that of old fashioned sexual psychology as exemplified by Havelock Ellis. While one cannot condemn such literature, it is rather unfortunate to find that recent dynamic studies in the fields of sociology and psychiatry have been largely neglected. Since the larger clinics, particularly those connected with domestic relations courts, find that the most important conflicts are in the psychologic sphere rather than in the physical, this book cannot be by any means the answer to the problem. It is fairly well written, although not very well organized. It is neither specific enough to be of much value to the newly married couple, nor general enough to serve as a guidebook for the expert who wishes to interest himself in this field.

La malaria en Guatemala: Estudio epidemiológicos y desarrollo de la campaña antipalúdica. Por M. Gagliardo Mira. Paper. Pp. 54, with 7 illustrations. Rome: Stamperia Moderna S. A., 1936.

To the south of us, in Central America, lies Guatemala, a land of many contrasts and many public health problems. Along the coasts of the Atlantic and the Pacific the territory is flat and characterized by the lush tropical growth commonly associated with tropical diseases. Much of the interior is mountainous, with many citizens residing in altitudes of 10,000 feet or more. In these volcanic ash covered highlands live the majority of the Mayan Indians, who make up 85 per cent of the population. In the lowlands, malaria constitutes an omnipresent public health problem. In the highlands, the absence of sufficient iodine in volcanic soil paves the way for an enormous incidence of goiter. Almost universally in this land, parasitic worms infest mankind and are tolerated as a no less essential part of the body than are the fingers or ears. The present publication deals with epidemiologic studies of malaria and the inauguration of the present antimalaria campaign.

Sections of this report are devoted to mortality and morbidity statistics, splenic and parasitic indexes, the geographic and biologic distribution of mosquitoes, the influence of local factors, the distribution of various clinical forms of malaria, the details of antimalaria campaigns, the difficulties of the application of quinine therapy and the creation of public health measures directed to the application of control provisions. About the year 1931 the splenic index along the Atlantic Coast lowlands suggested an incidence of malaria in excess of 91 per cent; in nearby areas the parasitic index approximated 97 per cent.

Since the period of collecting material that led to this report, improvements have been made in the general public health situation in Guatemala, including malaria control. A national health building has been erected in Guatemala City and additional studies have been made as to the distribution of mosquitoes. It has been determined that contrary to previous views malaria-bearing mosquitoes may be found at much higher elevations than the two and three thousand foot elevations heretofore regarded as the upper limit of flight. All in all, this publication reflects the intelligent, far-flung efforts of a disease-ridden country to protect its people through high types of public health conservation measures.

Surgical Anatomy of the Head and Neck. By John Finch Barnhill, M.D., F.A.C.S., LL.D. Introduction by Paul S. McKibben, Professor of Anatomy in the School of Medicine, University of Southern California. Cloth. Price, \$20. Pp. 921, with 431 illustrations. Baltimore: William Wood & Company, 1937.

This monumental work, based on the author's long experience as a teacher of otolaryngologists in graduate courses, not only is a colloquial, interesting and accurate guide for surgical dissection of the head and neck but also epitomizes the steps of selected types of operative procedures, describing them as the various structures are reached. Numerous variations and anomalies are pointed out, notably in the cranial venous channels, the sphenoid sinuses, the temporal bone and the cervical circulation. A remarkably clear account of the cranial nerves is included. The latter half of the book comprises 431 full page illustrations and diagrams, nearly all made by Dr. Barnhill from his own dissections with the utmost accuracy of detail and accompanied by long explanatory captions as well as references to the preceding lectures. Thus they may be reviewed quickly from the captions or studied systematically in connection with the text or as a guide to work on cadavers. The index, while brief, is adequate. The proofreading has missed a number of transposed letters and misspellings of proper names, requiring

correction in later editions. The type is large and the typography and format are otherwise excellent. Lacking the lithographic elegance of professional illustrators, these drawings, like those of Mosher and Jackson, are more valuable because they are made by one who knows what to look for and emphasize. Dr. Barnhill deserves special commendation for his indomitable courage in completing his textbook and drawings during long months of disabling and painful illness. This book will be invaluable to all otolaryngologists and students of that special field. It contains many suggestions, particularly as to surgery of the neck and of the cranial cavity and sensory nerves, of great importance to general surgeons. Dedicated to the Research Study Club of Los Angeles, which underwrote publication, this is a fitting culmination to Dr. Barnhill's long and active life as a practitioner and teacher.

The Biology of Human Conflict: An Anatomy of Behavior, Individual and Social. By Trilant Burrow, M.D., Ph.D., Scientific Director, The Lifwynn Foundation, New York City. Cloth. Price, \$3.50. Pp. 435. New York: Macmillan Company, 1937.

The author of this volume is one of the lesser known but nonetheless intense students of the problems of human behavior. For many years he has been conducting, in as scientific a fashion as possible, a small laboratory in New York, where he is attempting to demonstrate—apparently with some degree of success—the fact that no single school of psychoanalysis or of its near relatives is entirely satisfactory. In a previous work Burrow showed that the domination of the analyst over the patient was anomalous and that for therapeutic and investigative purposes the relationship might well be reversed or, better still, that there should be no domination by either. This particular type of psychoanalysis he calls phyloanalysis, because it is carried on with a number of individuals who are coordinate in analyzing one another in order to attempt to show racial (in the larger sense of the human race) tendencies. In the present volume he attempts to tie together a number of observations which he has made in order to demonstrate this unique type of behavior dynamics.

The application of a new understanding of neurotic mechanisms, which Burrow brings to the reader in this book, shows its application to a number of different spheres, such as legal medicine, in which the concept of right and wrong is broken down in a fashion rather unique and apparently quite level headed, or as in neural physiology, wherein the internal environment of the individual is demonstrated to have quite a bearing on his thinking processes and his ability to avoid neurotic behavior and tendencies. The analysis of much of the psychologic thought found in modern psychopathology is critically reviewed and, according to the author's tenets, definitely praised when deserving and criticized when not. Symbol formation is deeply studied, analyzed and shown to be of extreme importance. Burrow's concept of the symbol is much broader than that of Freud, and much of the action and interaction of the individual is shown to be dependent on it. The volume contains an immense amount of meaty discussion. The dynamics which Burrow discusses is complex yet in his presentation seems to have an existence in fact, and throughout the volume a good understanding of the general field of psychopathology is demonstrated. There are many statements about which the conventional psychoanalyst or perhaps the conventional psychiatrist will be likely to differ.

There are parts of the book which are very difficult to read because of the author's style. The sentences are involved and he uses a vast vocabulary, which he attempts to render more accessible by a short and none too clear glossary at the end of the book. In his introduction, Burrow points out that it is impossible to divorce emotional from the intellectual understanding of any problem. While a man may be intellectually willing to accept certain facts, his whole emotion and symbolism will prevent him from being an adherent to the school which presents those facts because of his emotional background. In this light Burrow implies that the attitude of those who criticize his work because of its rather poor readability is like that of the uncooperative Freudian patient toward the analyst. In this he is not correct. There seems to be no question that much of his ideation is of importance in aiding psychiatric thinking and the

understanding of the workings of the mind, but there is a way of overlooking the fact that Burrow's style is cumbersome and his terminology intricate. Nevertheless, the existence of the phyloanalytic school of psychopathologic thought might just as well be accepted and studied. It is questionable whether it will supplant the better understood schools, but it is active, logical and in many ways scientific.

Das Arsenvorkommen bei Reichenstein und die sog. Reichensteiner Krankheit. Von Prof. Dr. Johannes Käthe, Direktor des Staatl. Meznal-Untersuchungsamts, Breslau. Veröffentlicht von der Schlesisch-Gesellschaft für vaterländische Cultur. Paper. Pp. 24, with 12 illustrations. Breslau: Ferdinand Hirt, 1937.

This little booklet is largely now a historical and toxicologic document, owing to the fact that for the last nine years development of a pure water supply has caused the disappearance of the "reichenstein sickness," which, it came to be known, was nothing more or less than arsenical poisoning, of which many cases occurred in this region owing to the arsenic contamination of the drinking water as well as to occupational exposure to arsenic-containing ore. In addition to the usually described symptoms of chronic arsenical poisoning, it is of particular interest to note the frequency with which malignant neoplasms developed from arsenical warts, one local physician asserting that half of all the patients suffering severely from the Reichenstein sickness died of carcinoma.

A Monograph on Veins. By Kenneth J. Franklin, D.M., M.R.C.P. University Demonstrator of Pharmacology, Oxford. Cloth. Price, \$6. Pp. 410, with 46 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1937.

This is a truly remarkable treatise on veins by a scholar, an original investigator and a curious seeker of truth. Such a monograph on veins has never before been produced in English. The author has been actively engaged in research on the venous system for many years and has now made available to others a vast literature, all of which has a definite bearing on physiologic, pathologic and clinical problems. A short, concise historical sketch on the development of knowledge with regard to the veins is followed by chapters on the embryology, the functional anatomy, the valves of veins, the circulating volume of blood, the comparative anatomy of veins, the venules, the absorption and diffusion from veins, the innervation of veins, their relation to chemical stimuli, the heart and venous return, the effects of hydrostatic pressure and muscular contractions, venous pulsation, respiration and venous return, venous pressure, and the movements of blood in the veins. Two short chapters are added on clinical applications. It is obvious from this summary of contents that the review is primarily intended for those engaging in experimental and clinical research. In fact it is the best and most timely presentation of the anatomy and physiology of circulation, with special emphasis on the venous side. Perhaps one might wish for a broader exposition of the clinical problems encountered because, after all, the aim of all research is a better understanding of and a more logical approach to human ailments. Nevertheless, the author has succeeded in formulating from a scattered literature an integrated whole supported by a complete bibliography. The printing and illustrations are excellent. The monograph will be a source of keen pleasure to every physician who tries to look for fundamental knowledge and not for short cuts in medicine.

Veröffentlichungen aus der Konstitutions- und Wehrpathologie. Herausgegeben von L. Aschoff, W. Ceelen, W. Koch und P. Schürmann. Geleitet von W. Koch. Heft 40. Band IX, Heft 3: Bericht über das Ergebnis der Obduktion des Gorilla Bobby des Zoologischen Gartens zu Berlin: Ein Beitrag zur vergleichenden Konstitutionspathologie. Von Prof. Dr. Walter Koch. Paper. Price, 2.50 marks. Pp. 36, with 17 illustrations. Jena: Gustav Fischer, 1937.

This is a rather lengthy report of the postmortem examination of a male gorilla about 10 years old, the principal changes being found in the appendix and lungs. An acute attack was superimposed on an old appendicitis, with perforation and periaepical abscess; in the lungs, hemorrhagic edema was noted with the presence of lymphocytes. The pulmonary changes were thought to be due to the aspiration of water. The presence of calcium casts in the collecting tubules of the kidneys was especially stressed. The hypophysis, which weighed about twice as much as that of a human being, was considered enlarged, and the testes were undeveloped and atrophic, without evidence

of spermatogenesis. Since the gorilla was rather obese, adiposogenital dystrophy was considered. Though the necropsy report is interesting, the purpose of a special publication in pamphlet form is not quite clear.

Diagnosis and Treatment of Malignant Tumors. Syllabus for Postgraduate Course. Tumor Clinic, Stanford University School of Medicine. Paper. Pp. 82, with illustrations. San Francisco, 1937.

This syllabus, adopted by the Stanford University School of Medicine, is excellent. The only criticism found in the entire syllabus was under the heading "Public Education and Cancer." Speaking of the drive made by the American Society for the Control of Cancer in regard to lay education, the author observes, "One wonders whether such a drive is not likely to do as much harm as good in the present state of our ignorance regarding cancer." The syllabus covers the entire field of cancer and can be highly recommended as an outline for a postgraduate course. It would also be worth while for any one interested in the cancer problem to obtain this syllabus and read it carefully.

Miscellany

SPECIAL REPORT OF PNEUMONIA ADVISORY COMMITTEE TO SURGEON GENERAL, U. S. PUBLIC HEALTH SERVICE

Although a large amount of work has been done, particularly in the past two decades, on pneumonia and problems related to it, the disease continues to rank high among the common causes of death in this country. From the standpoint of the health of the community, one of the greatest recent advances has been the introduction of generally available facilities for rapid typing and the provision of certain specific therapeutic pneumonia serums by a few states and cities.

STANDARDIZATION OF TYPING SERUMS AND CULTURE COLLECTION

The classification of pneumococci as types I, II and III and Group IV by Dochez and Gillespie years ago and the later subdivision of the latter group into at least twenty-eight¹ additional specific types by Cooper and her co-workers has afforded important means of studying many of the problems presented by pneumonia.

To safeguard progress thus far made, it is essential that all typing serums produced be uniform as to their specificity. Adequate precautions should be taken by some governmental agency, and preferably the Public Health Service, to insure by suitable tests and other necessary means the strict specificity of all the diagnostic serums produced in or introduced into this country regardless of whether such serums are prepared for domestic or for foreign consumption. As an important corollary, a collection should be maintained of cultures of each of the types of pneumococci for which diagnostic serum is now available.

STANDARDIZATION OF THERAPEUTIC SERUMS

Methods of standardizing the potency of therapeutic antipneumococcus serums should be rapidly developed and made uniform. The application of specific serum therapy to type V, VII and VIII cases will be hindered and handicapped so long as the potency of these serums cannot be uniformly measured and some reliable recommendation made as to the size of the average dose needed. It is desirable in addition to cooperate with the League of Nations committee on the standardization of biologic products in an effort to establish reliable international potency standards for all antipneumococcus serums used for therapeutic purposes.

Manufacturers of serums for any type for which a standard has been set should be required to comply with the regulations and forbidden to dispense, by sale or otherwise, serums of such types for clinical use unless they comply with the regulations adopted. This matter might well be handled by the National Institute of Health.

1. Cooper considered types VI and XXVI so much alike that she combined them and called the resulting type type VI; in some instances this combination is referred to as type VIa and b. Recently other investigators have also regarded types XV and XXX as similar. There is not uniform agreement as to this, however.

PRODUCTION OF THERAPEUTIC SERUMS

Attention should be directed to improving the materials used and the methods and schedules of immunizing animals so as to increase the quantity of antibody produced and lower the cost. Investigations of antibody production in rabbits can be made in almost any suitably equipped laboratory. When work of this nature is carried out in horses, however, progress is necessarily slow. In consequence, to facilitate such studies in the latter animal it would seem advisable for the Public Health Service to give what advice, technical assistance and financial aid is possible to those public laboratories already engaged in the manufacture and distribution of antipneumococcus horse serums. There is also need of improving the methods of serum concentration and refinement, which might best be handled in those public laboratories already involved in such work and which possess the clinical facilities for adequate trial.

The chemical and physical characteristics of antibody should be further defined with a view to determining the nature of its specifically reactive groups and the possibility of synthetic antibody production.

SURVEY OF FACILITIES FOR PRODUCTION OF SERUM

Surveys should be made of the potential therapeutic pneumonia serum output of public and private laboratories. If many states and large cities promptly undertake to supply therapeutic pneumonia serums for all patients, or even for indigent patients in their jurisdiction, it is possible that a shortage of these products might develop. It is possible that, if some responsible agency would contract for a large volume of therapeutic pneumonia serum, the contract to cover a minimum period of about three years, the cost of such serums might be substantially reduced below that prevailing today.

FELTON'S ANTIGEN

The preliminary figures obtained as a result of the immunization of many thousands of men in various CCC camps with derivatives of certain types of pneumococci referred to as "Felton's antigen" suggests that this material may be of value in reducing the incidence of pneumonia. This investigation should be continued and attention should also be given the possibility of carrying out the experimental immunization of a selected civilian population of considerable size. It would seem advisable that adults of all ages be included, that the past pneumonia record of the group chosen be known, and that careful record be kept of all cases in the immunized and control groups for at least six consecutive months. All respiratory infections in both groups should be determined. Adequate facilities should be available for carrying out the clinical and bacteriologic diagnosis of such infections. Certain antibody studies on the blood of individuals in the immunized and control group would be highly desirable.

EPIDEMIOLOGIC STUDIES

From limited studies of normal persons with respect to their carrier rate of pneumococci, it was found that at a given time pneumococci of some type may be present in the nasopharynx of about 40 to 50 per cent of normal people. The incidence is known to increase during the colder months of the year. In addition, a large proportion of all normal people may carry some type of pneumococcus in their nose or throat at some time during each year. Most of the strains carried, however, are representatives of those types least often found in pneumonia.

Observations in a few studies of a small number of families have suggested that when pneumonia due to one of the more virulent types, such as type I, occurs in an individual, about 20 per cent of the other members of the patient's family also are carrying the same type in the nose or throat. When acute infections of the upper respiratory tract, such as colds, are prevalent among the family contacts, the incidence of homologous type carriers may approach 70 or 80 per cent.

The evidence to date suggests that a pneumococcus of a given type may be carried into the family group by one individual, where it rapidly spreads to several members of the family, and at times some one or more individuals within the group may subsequently come down with pneumonia due to that organism. If this is so, it would do little good to insist on the strict isola-

Dr. Robert Helig

S. M. S. Medical College

32635

tion and quarantine of the patient in an effort to prevent the patient's spreading the organism to other members of the family, for many of the latter have already become carriers of the same type. As this matter may affect administrative procedures aimed at controlling the prevalence of pneumonia, it is highly desirable that the question be studied further and that conclusive evidence be obtained of the usual means by which infection is spread both inside and outside the family group.

Several thousand normal persons might be examined periodically for several months to determine the carrier rate of pneumococci of various types. The family contacts of a large number of typed cases of pneumonia might be studied in similar fashion. In addition there is need to pay particular attention to the study of the carrier rate of pneumococci in persons with infections of the upper respiratory tract at the time and in those having pathologic conditions of the mouth, throat, nose and accessory sinuses.

Outbreaks of pneumonia in institutions and small communities may be studied with profit, as little is known of the natural history or usual course of epidemics of this nature. Some evidence has appeared, however, suggesting that the general immunization of the exposed population in institutional epidemics may be of use in aborting the outbreak. Some attention should be paid to means of eradicating the condition in healthy carriers. The preliminary results of studies of this problem in animals suggest that local treatment (washing the nose and throat with specific serum) plus general bodily therapy (parenteral administration of specific serum) is necessary to overcome the carrier condition. The use of Felton's antigen or other immunizing agent might be considered in conjunction with local measures.

STUDY OF ETIOLOGY AND INCIDENCE OF PNEUMONIA

The true frequency of pneumococcal pneumonia, both primary and secondary, in a city, country or larger political unit has never been accurately determined. Arrangements might be made in several communities, preferably in various sections of the country, to set up special pneumonia studies. The importance of case finding is great, and special reporting facilities, which might embrace contact at intervals of a day or two with every physician in the area, should be provided. Over a period of one, two or more years every case of pneumonia, both primary and secondary in each area studied, should be exhaustively studied bacteriologically. Concurrent studies of pneumococcus carriers in the communities investigated would appear to be of great value. Evidence relating to the influence of host factors in current cases should be obtained and carefully analyzed.

SULFANILAMIDE

The results thus far obtained from the therapeutic use of sulfanilamide in animals infected with pneumococci appear sufficiently impressive to warrant further and extensive investigation of the pneumococcal power of this compound and related or other compounds. Whenever it seems advisable, clinical trial of such substances with or without the simultaneous administration of specific immune serum should be made on a fairly extensive scale, with careful controls for comparison.

MORTALITY STUDY

A statistical study should be made of the deaths in which pneumonia is reported as a secondary cause to determine the influence of age, sex, occupation and associated factors in an effort to distinguish differences between such deaths and those certified as being due primarily to pneumonia.

CLASSIFICATION OF DEATHS

The Manual of the International List of Causes of Death, 1929, provides for the following classification: 108, Pneumonia lobar-pneumococcus pneumonia. The Instruction Manual of the Bureau of Census, Department of Commerce, issued Sept. 15, 1937, includes the following recommendation for coding—page C 10—insert or correction—pneumonia types (I to IV 108). It is suggested that the Bureau of Census be asked to recommend that deaths from all types of pneumococcal pneumonia (I to XXXII) be coded under 108 lobar pneumonia, unless, in addition to the type, information is given that the death was due to bronchopneumonia.

PNEUMONIA STATISTICS IN PUBLIC HEALTH REPORTS

The current weekly state reports published in *Public Health Reports* do not include pneumonia. The weekly reports from cities include pneumonia deaths but not cases. It is suggested that consideration be given to including pneumonia cases in state reports and pneumonia cases and deaths in city reports. Such a procedure might stimulate better case reporting.

PNEUMONIA PROGRAM QUESTIONNAIRE

To determine which communities have undertaken pneumonia programs of various sorts and the extent of their efforts in this direction, it is advisable that questionnaires be sent to the departments of health of the various states and to those of cities of 100,000 population or over. This may yield information of value for directing further work of this nature. Similar surveys might be made annually for the next few years.

CONSULTATION SERVICE

It is desirable that the Public Health Service offer a special consultant service to departments of health or other organizations wishing to start pneumonia control programs. With advice of this kind, most communities in which an active interest exists can do a great deal for themselves toward the development of a sound pneumonia program at a minimum cost. The departments of health of states and large cities as well as the medical societies in the corresponding areas should be informed of the availability of this consultation service.

FINANCIAL SUPPORT OF PNEUMONIA PROGRAMS

In addition to lending all possible encouragement and aid to responsible groups wishing to start pneumonia programs, it would seem suitable that a portion of the money made available through the Social Security funds be expended for the support of sound community-wide programs of this kind.

PUBLICITY

The emergency character of pneumonia and the need to restrict activity and avoid exposure and excesses when experiencing a cold or other minor respiratory infection need to be stressed, as well as the importance of prompt medical care when serious symptoms develop. For the medical profession publicity should deal largely with the importance of early typing and early serum treatment in suitable cases, with mention of the desirability of suitable nursing care. The need of careful general medical treatment should also be discussed, which might include present day views of the value of such things as oxygen, diathermy, pneumothorax therapy, chemotherapy and possibly diet, liquids, cathartics and digitalis.

THE TRAINING OF TECHNICIANS

Laboratory technicians assume a position of extraordinary importance in the conduct of pneumonia programs. Many training schools for technicians do not give adequate instruction in pneumococcus typing. The performance of one or two typings is not sufficient for this purpose. Efforts should be made to call this matter to the attention of officials of the associations of pathology, clinical pathologists, public health laboratories and certified technicians and, wherever advisable, to the authorities responsible for the training of technicians. Accuracy in bacteriologic diagnosis, pneumococcus typing and blood culture work is absolutely essential for the successful control of pneumonia mortality by specific serum therapy.

HEALTH SURVEY CASES

Any available data obtained during the health survey and referable to the morbidity of pneumonia should be studied and analyzed in detail. The possible role of factors such as economic status and occupation in influencing the pneumonia attack rate in these cases needs investigation.

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Faith Healing as the Practice of Medicine.—The defendant, Valeria Klinger, was convicted under two counts of violating the provisions of the medical practice act of Illinois and appealed to the appellate court, third division, first district.

An investigator for the department of registration and education testified that she called on the defendant and complained that her arm would repeatedly go out of joint, that the defendant manipulated her shoulder muscles and also worked on her back, that the defendant then seemed to go into a trance, folding her hands as if in prayer, and that she paid the defendant \$1 for the treatment. The defendant testified that she had belonged to the First Spiritualist Church of Cicero for five years and that she was a qualified healer of that church. She did not, she testified, sell any medicine or give it away or prescribe it, or practice surgery. She simply prayed for divine healing and healed through prayer. She denied having treated the investigator. A witness for the defendant, C. A. Burgess, testified that he had been president of the Spiritualist Association of Illinois for twenty-seven years, that it was a regular church incorporated under the laws of the state of Illinois, and that the defendant was a healer of the church. Healers, he testified, are examined by the board of examiners of the church and are given certificates authorizing them to practice.

The Illinois medical practice act, the court pointed out, excludes from its provisions "persons treating human ailments by prayer or spiritual means as an exercise or enjoyment of religious freedom." The evidence in the present case, the court thought, clearly showed that the defendant's method of curing was by prayer, that she was a duly authorized member of the First Spiritualist Church of Cicero, and that her license was issued by the Spiritualist Association of Illinois. In the opinion of the court, her activities came within the exemption contained in the medical practice act relating to persons treating human ailments by prayer or spiritual means. The judgment of conviction was therefore reversed.—*People v. Klinger (Ill.)*, 11 N. E. (2d) 40.

Diseases: Amebic Dysentery Attributed to Fly in Soft Drink.—The plaintiff, a girl 13 years old, drank a portion of a bottle of a soft drink in which, it was contended, there was an infected fly. She became violently ill and remained sick for some three months, at which time a diagnosis of amebic dysentery was made. Attributing the disease to the negligence of the appellant bottling company, the girl, suing by her father as guardian and next friend, recovered a judgment against the company for \$7,500, whereupon the company appealed to the Supreme Court of Arkansas.

A physician who had treated the child testified, in answer to a hypothetical question, that if he had a patient on June 17, 1936, who was in good health and was normal in every particular, and on that occasion she drank two thirds of a bottle of a soft drink and immediately started to vomit, and vomited all night, and that, after that vomiting, she started to lose weight and would pass off mucus, and continued to do so until the time of the trial, and if there was a fly in the soft drink, and the fly had on it the organism that causes amebic dysentery, he would attribute the disease to the fact that the child drank the soft drink with the fly in it. He further testified that anywhere from four days to three months would be required to develop amebic dysentery after the organism had been received in the system. He did not testify that the fly in the bottle had the organism on it, nor did any other witness. Another physician testified that he had attended the child and that he had taken some of the remaining portion of the soft drink and sent it to the state laboratory, which reported that no parasites were found in it. The witness stated, however, that he did not always rely on negative reports of any laboratory tests and did not regard the test made as conclusive.

Proof, said the Supreme Court, of the fact that a fly was found in the bottle, and that flies do carry the organism that causes the disease from which the girl suffered, did not suffice to support the verdict. It was mere conjecture that the fly found in the bottle was a carrier of the organism and had communicated the disease to the girl. The only definite proof with respect to the contamination of the drink was to the effect that no parasites were found in it, and while it may be true, the court said, that the test made was not conclusive, the fact remains that it was the only testimony on the issue of fact. It was mere surmise and conjecture to say that the portion of the drink consumed by the girl was in fact infected, while the remaining portions of the drink were not. The Supreme Court, therefore, reversed the judgment and remanded the cause.—*Coca-Cola Bottling Co. of Southeast Arkansas v. Bell (Ark.)*, 109 S. W. (2d) 115.

Prenatal Injuries: Liability for Death of Infant Injured Prenatally.—Where an infant suffers prenatal injuries through the negligence of another which result in its death three months after birth, the person responsible therefor is not civilly liable, in the opinion of the Supreme Court of Michigan, either at common law or under the Michigan Survival Act. In this case, it was alleged that by reason of the accident, which occurred twenty-two days prior to birth at the end of the normal period of gestation, the infant suffered injuries to his skull causing hydrocephalus and brain hemorrhage, resulting in death. The Supreme Court reversed the judgment of the trial court denying the motion to dismiss the action.—*Newman v. City of Detroit (Mich.)*, 274 N. W. 710.

Malpractice: Patient Burned by Infra-Red Lamp.—The patient in this case seriously crushed and bruised the flesh of his left thigh and was taken to the appellant physician's hospital for treatment. Opiates were administered to relieve his suffering and hot compresses were applied to the injured part, consisting of towels saturated with a hot saline solution and covered with a rubber sheet over which a dry towel was placed. A 500 watt incandescent infra-red lamp was then applied to the injured part through the compresses, the lower rim of the lamp being suspended at a distance of 21 inches from the thigh of the patient. This treatment was instituted about 1:30 in the afternoon. At 2:30 codeine was administered and the patient then became unconscious and remained so until 5:30 in the afternoon. At that time it was discovered that he had sustained a third degree burn. He subsequently brought suit against the appellant physician and the nurse who had personal charge of him. The trial court exonerated the nurse but the jury rendered a verdict against the physician for \$50,000, which, on motion for a new trial, was reduced to \$25,000. The physician then appealed to the district court of appeal, third district, California.

According to the evidence, neither the compress nor the lamp was changed or removed from 1:30 until 5:30 p. m. The physician, whose office was across the hall from the room occupied by the patient, visited him occasionally during this four hour period. About 4:30 the nurse asked the physician whether the lamp or compress should be changed and he advised her to leave them as they were until after the patient's evening meal. The evidence was undisputed, the court said, that tender, devitalized flesh is much more susceptible to burning from excessive heat than is normal flesh. Qualified physicians testified that the third degree burn which was suffered by the patient was the result of subjecting the tender, devitalized flesh of the bruised thigh to excessive heat from the infra-red lamp for too great a length of time. There was evidence that the lamp generated 140 degrees of heat in an hour, and that not more than 110 degrees Fahrenheit should have been applied under the circumstances. The witnesses testified that the treatment of the injury which was administered by the appellant physician was not in accordance with approved medical practice of competent physicians in that vicinity. In the opinion of the court, the evidence justified a finding of negligence on the part of the physician.

The exoneration of the nurse from negligence did not necessarily relieve the physician from liability. Under the circumstances of this case, the court said, the nurse was presumed to

attend the patient under the supervision and direction of her employer, the physician. It was the duty of the physician in his treatment of the patient to see that the compress and lamp were used in such a manner as to prevent the application of excessive heat and consequent burning of the flesh. The supervision of the physician was shown by his personal visit to the room of the patient and by the inquiry of the nurse addressed to him an hour before the burn was discovered as to whether she should not then change the compress, to which he replied "leave them until after his evening meal." The physician was therefore not relieved of liability because of the verdict favorable to his codefendant, the nurse.

The trial court properly instructed the jury at the request of the plaintiff respecting the doctrine of *res ipsa loquitur*. In the present case the patient was burned in some way unknown to him, as a result of the treatment of his injury by the physician. It occurred while he was under the influence of opiates which prevented him from knowing just what caused the burn. The doctrine of *res ipsa loquitur*, therefore, was applicable to the facts of the case.

It was not prejudicial misconduct for the patient's attorneys to offer in evidence a letter written by the physician to the adjuster of an insurance company, although the letter tended to prove that the insurance company may have been interested in the outcome of the litigation. The letter was competent evidence to show that the physician had previously made a statement in writing which was in conflict with his testimony at the trial. If evidence is competent because it is addressed to a valid issue in the case, it is admissible even though it may incidentally disclose the fact that an insurance company is interested in the outcome of the litigation.

The appellate court could find no prejudicial error in the record and therefore affirmed the judgment of the trial court for the plaintiff.—*McCullough v. Langer (Calif.)*, 73 P. (2d) 649.

Workmen's Compensation Acts: Collapse of Lung Attributed to Strain.—The employee in this case was engaged in polishing hoods for automobiles for the appellant corporation. Overhead conveyors, moving constantly and approximately seven feet from the floor, carried the hoods to and from the table at which the employee worked with a partner. In lifting a hood to the conveyor the employee, who as a general rule hung the hoods back on the conveyor after they had been polished, did so in such a manner as to cause his left arm to be extended in an upward position. On Sept. 12, 1936, at about 11 a. m., while in the act of lifting a hood to the conveyor, the employee felt a severe pain in his left side. He sat down for a short period and besides feeling the pain in his left side he perspired, had a shortness of breath and felt "awfully sick." The pain was of a short duration, however, and he continued to work until noon. The pain started again between 1:30 and 2 p. m., and the employee worked at intervals from that time until 3 o'clock, at which time he went home. A physician was summoned on the morning of September 13 and, receiving no relief, the employee called in another physician that same evening, who had him removed to a hospital. This physician testified that the employee had suffered a collapsed lung, which in his opinion took place at the time the employee first experienced the pain, September 12, that both air and blood were found in the pleural cavity, that there was a rupture of an emphysematous bleb or bulla, that the strain and exertion in lifting the hood caused the rupture, and that the employee's condition of total disability was fairly permanent. On behalf of the employer, medical testimony was introduced to the effect that the condition of the employee was one which would occur as the result of an abnormality of the lung without other demonstrable causes. The industrial board awarded the employee compensation under the workmen's compensation act and the employer appealed to the appellate court of Indiana, in Banc.

Here, said the court, the employee experienced a pain while in the act of lifting a hood to the conveyor, and his injury was traced by medical testimony to the act of lifting. The mere fact that the physical condition of an employee might make him more susceptible to the particular injury which resulted in his disability is no reason for holding that a disease or condition,

rather than the accident, was the proximate cause of the injury on which the allowance for disability was based. Not all workmen are constituted alike. Some are stronger than others and more capable of doing the same work. Some would use more exertion or effort in performing the same labor and, because of their physical condition, might be more susceptible to injury. The act of lifting the hoods to the conveyor undoubtedly required some physical effort and exertion which the industrial board found contributed to the injury complained of. While the work required of the employee may be characterized as ordinary, and such work may have been accomplished by other employees without injury, yet his injury was attached to a definite occurrence incidental to his employment and within the well defined meaning of the term "accident," as used in the workmen's compensation act. The court, therefore, affirmed the award of compensation.—*Studebaker Corporation v. Jones (Ind.)*, 10 N. E. (2d) 747.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Determination of Exercise Tolerance by Two-Step Test. J. A. Reisinger, Washington, D. C.—p. 341.

Attempt at Immunization Against Rheumatic Fever.—Wasson attempted to immunize thirty-four children who have had attacks of rheumatic fever with stock filtrate of Streptococcus haemolyticus. Ten children received inoculations with the filtrate from September 1933 to June 1935 and twenty-four children from September, 1935 to June 1937. Thirty-four patients were used as controls. The only criterion used for selecting the patients for treatment was their willingness to cooperate during the protracted course of inoculations, involving weekly and monthly visits to the clinic. Subcutaneous injections were first given weekly in graduated doses of 0.3, 0.6 and 0.9 cc. beginning with the 1:100 dilution, followed by similar doses of stronger concentrations. After twelve injections a month was allowed to elapse, at the end of which time 0.3 cc. of the full strength filtrate was given, followed at monthly intervals by 0.6 and 0.9 cc. The latter dose was repeated monthly until the beginning of June. The treatment was then discontinued until September, when the whole course was repeated as before. The thirty-four children who received inoculations of hemolytic streptococcus filtrate fared well as compared with the untreated groups and even with the average health experience of any group of normal children. Whether this was due to treatment or to a fortunate chance selection of patients cannot be stated. Of thirty-four children only two, or 5.9 per cent, had the disease in its acute phase during the course of treatment, while two control groups showed 15 per cent and 43.4 per cent, respectively. The physical condition of the control patients remained mediocre, and complaints of pains, headaches and fatigue were frequent.

Intraspinal Injection of Vitamin B₁ for Intractable Pain.—In determining the feasibility of intraspinal injections of synthetic vitamin B₁, Stern made experiments on cats; since then 120 intraspinal subarachnoid injections in doses from 500 to 50,000 international units (from 1 to 100 mg.) were given to twenty-eight patients with inoperable cancer, von Recklinghausen's disease, multiple sclerosis, degeneration of the pyramidal system of unknown etiology, thrombo-angiitis obliterans with pregangrenous condition of the feet, duodenal ulcer with pulmonary tuberculosis, alcoholic neuritis of the supra-orbital nerve and of the sciatic nerve, cardiac decompensation, uremia, anuria, tabes dorsalis, hypertrophic spondylitis, osteoporosis of the spine, Paget's disease, intractable pruritus ani and vulvae, beriberi and acute poliomyelitis. The beneficial effects of intraspinal vitamin B₁ appear much quicker than when given by other routes, because the vitamin remains in the cerebrospinal fluid for several days after a direct intraspinal injection. Improvement in varying degrees was noted in all patients: all felt better and looked better; appetites were increased, pain was lessened or abolished, muscular control, speech and gait improved, the joints became looser, libido was increased and diplopia was corrected. The case of multiple neurofibromatosis responded most favorably. Besides marked general improvement, some nodules became softer and smaller and some have disappeared. Treatment should start with 10 mg. and be increased every fourth to seventh day, or more frequently in urgent cases. No patient had any paralysis, anesthesia or signs

of meningitis following the injection. Spinal fluid cell counts were not appreciably increased. The hydrogen ion reading of the spinal fluid was usually reduced. In all cases showing a pH above 8.5, treatment should be pushed, but it is inadvisable to reduce the pH below 7, since restlessness and nervousness may ensue. Uncontrolled intraspinal administration may cause "vitamin B₁ poisoning," which, as demonstrated experimentally, may prove fatal.

Fever Therapy in Acute Rheumatic Fever.—Dunn and Simmons comment on fifteen cases of acute rheumatic fever treated by fever therapy, three of which were complicated by chorea; thirteen patients became symptom free, three had relapses and one showed moderate improvement although there were still rheumatic manifestations three months after forty-eight hours of fever between 103 to 105 F. Salicylates were given to twelve patients over periods of from six days to seven weeks before fever therapy was tried. Fever therapy reduced the symptomatic activity of rheumatic fever and in many cases the leukocyte counts and sedimentation rates became normal.

Relief of Diabetic Pain with Sodium Chloride.—Sandstead and Beams studied the effect of the oral administration of from 15 to 90 Gm. daily of sodium chloride on thirteen diabetic patients complaining of pain who had not been relieved by the usual diabetic management. The pain was of neuritic origin in ten and of arteriosclerotic origin in three. All the patients obtained complete or marked relief of the neuritic symptoms after the administration of sodium chloride. The relief of pain was accompanied by signs of improvement in the vascular disease in the patients with arteriosclerotic pain and by improvement in the circulation of those with neuritic pain, as shown by the histamine test. Ischemia, the result of vascular disease, primarily arteriosclerosis, appears responsible for the neuritic symptoms. The oral administration of sodium chloride appears to be the rational treatment for the neurocirculatory complications of diabetes.

Granulocytopenic Fraction of Yellow Bone Marrow.—Marberg and Wiles gave four patients with leukopenia and six with agranulocytic angina (malignant neutropenia) yellow bone marrow concentrate orally; all recovered. Those with acute leukopenia showed improvement in about forty-eight hours. In no case was there a recurrence of the depression of the blood cells or clinical symptoms during the period of treatment. Clinical recovery in cases of leukopenia or agranulocytic angina coincides with or follows immediately after the restoration of a blood picture consistent with the severity of the local lesions. The results confirm the clinical observations of Watkins made with whole yellow bone marrow and establish the activity of a concentrate devoid of the bulky inert neutral fats which make whole bone marrow unpleasant for clinical use.

Hygroma Colli Cysticum and Hygroma Axillare.—Goetsch presents a study of twelve cases of cystic hygroma. In ten the growth involved primarily the cervical region and in two the axilla. The plausible theory of its etiology is that it arises from sequestrations of lymphatic tissue. In cervical hygroma, such sequestrations are derived from primitive jugular sacs which have failed to join the lymphatic system in the normal manner. Their potentiality of increasing in size is due

to the fact that these "lymphatic rests" retain their embryonic power of irregular growth. In the average case there are no local or constitutional symptoms, although there may be cosmetic disfigurement. Severe respiratory embarrassment may occur when the tumor extends into the mediastinum. The large hygroma has a tendency to become secondarily infected, and the infection may be followed by serious symptoms or even death. Anemia and a poor nutritional condition are occasionally noted in children. Hygroma is a benign, true neoplastic tumor of lymphatic origin. Histologic evidence is offered as a basis for the explanation of the manner of growth, development and destructive action of hygroma. Endothelial fibrillar membranes or sprouts from the walls of the marginal cysts penetrate the adjacent normal tissues. A lymphlike fluid is secreted within the fibrillae, which are thereby caused to spread apart and canalize. Minute cysts with an endothelial lining are thus formed within these sprouts. By continued secretion within, the cysts enlarge; by pressure atrophy of the walls between adjoining cysts, the large cavities characteristic of hygroma are formed. The fibrillar membranes infiltrate and circumscribe adjacent tissues. Muscle fibers, nerves or other anatomic units are thereby sequestered and destroyed either by direct atrophy and fatty degeneration or by being engulfed and disintegrated in the cystic fluid which is subsequently formed about them. Aspiration, simple incision for drainage and injection of sclerosing substances are futile in view of the multilocular nature of the tumors and the great danger of secondary infection. Radical surgical excision is the treatment of choice. There was one death. In one case there was a recurrence of the growth five months after the first operation. Late results following operation for hygroma were observed in five instances over periods of from ten months to ten and a half years. In a case of partial excision of a hygroma which was subsequently treated by high voltage roentgen therapy, the patient was in good condition fourteen months after operation. In the remaining five cases the immediate result was satisfactory but a late follow-up was not possible.

Prevention of Wound Disruption.—Thompson and his colleagues demonstrated that delay in healing of a wound in hypoproteinemic dogs may be prevented by promptly restoring the serum protein to a normal level after laparotomy and maintaining this level during the period of healing. In attaining this objective they used the plasma removed by plasmapheresis, which had been lyophilized and kept in the dehydrated state until just prior to its injection. Care was taken to supply all other known dietary factors in adequate amounts to the hypoproteinemic dogs. In three dogs subjected to bilateral laparotomy during the hypoproteinemic state, disruption of the wounds or failure to heal was not observed when the hypoproteinemia was controlled, after abdominal incision, by intravenous infusion of lyophilic plasma. Biopsy of wounds seven and fourteen days postoperatively had no similarity to the condition observed in hypoproteinemic dogs except moderate moistness, which was observed at the first biopsy. Considerable fibroplasia was evident seven days after the abdominal incisions. Determinations of total serum proteins gave values below the critical level for edema at the time of the original laparotomy and were elevated to within normal limits in seven days after six venoclyses of plasma. This level was maintained or elevated for the second period of seven days with four venoclyses of plasma. Sections of tissue removed on the fourteenth day showed firm fibroblastic repair and the intercellular edema present at operation had disappeared. The experiments demonstrate that healing of the wound can take place normally if the concentration of blood proteins is restored to normal and maintained there during the period in which the wound is healing. Deficiency of blood proteins retards healing and enhances wound disruption. The lyophilic process of preserving plasma described by Florsdorf and Mudd in 1935 provides plasma in such a state that it can be shipped to isolated communities and kept for months at refrigerator temperature. It can be given intravenously as a hypertonic solution. It rapidly replenishes the protein deficit and, being given as a hypertonic solution, it rapidly increases the osmotic pressure of the blood, thus effectively overcoming any tissue edema which may be present.

Snake Venom.—Swett used moccasin venom in six cases in the management of postoperative ocular hemorrhage. In the first case, hemorrhage occurred the first day following operation and continued to ooze in spite of all treatment for ten days. Moccasin venom stopped the oozing immediately after the first injection of 0.4 cc. As soon as the hemorrhage was checked, the blood disappeared rapidly from the anterior chamber and the wound was closed completely four days later. Identical results were obtained in four similar cases. The author has administered it only in those cases which showed a tendency to hemorrhage after operation and found that 0.5 cc. given daily for one week has been sufficient. He believes that the ideal method of its use would be to give these injections previous to operation to prevent the complications rather than to correct them. In one case of a severe iridocyclitis accompanied by hemorrhage in the anterior chamber, 0.5 cc. of the venom given subcutaneously stopped the bleeding. It also stopped the bleeding in the face of a severe inflammation in which no operation had been performed.

Pruritus Ani. J. T. Danis, Toronto.—p. 265.

Poliomyelitis.—McCormick advances the hypothesis of a vitamin B deficiency in an attempt to interpret the incidence of paralysis in poliomyelitis. Aside from the age, sex and seasonal incidence, which seem definitely related to the metabolic demand for vitamin B, the hypothesis would account for the spotty and relatively small incidence of paralytic symptoms, the lack of contagious relationship between such cases, and the recognized ineffectual control by quarantine. The infant and young child of today are amply supplied with vitamins A, C and D but no routine measures are employed to contravene vitamin B deficiency in the diet of young children at a time when rapid growth makes increased demands for this essential food element. No data are submitted in support of the theory advanced, but, if its basis is sound, it would appear that a fair clinical trial should be given to this natural nerve-protective agency, which has proved to be effectual in the treatment of other paralytic conditions of undoubted similarity. The most hopeful application of the theory advanced should be in prophylaxis and during convalescence rather than in the acute invasional stage of the disease.

Spontaneous Morning Alkaline Tide.—Barnett and Blume investigated the spontaneous morning alkaline tide in two normal subjects. With the subject at rest, without water or food, a curve of excretion of free fixed acid or alkali was obtained which may be regarded as basal under the conditions of the experiment. After about two hours during which there was a fairly constant rate of acid excretion, deviation of the curve in the direction of alkalinity began and continued to a maximal output of free alkali at from five to five and a half hours after waking. This period of spontaneous alkali excretion may continue until late in the afternoon, the initial morning level of acid excretion not being reached until 9 p. m. When diuresis was produced by drinking water, the period of diminishing acid excretion

began about an hour earlier. Strenuous exercise on the previous day resulted in almost complete obliteration of the morning alkaline tide. A short period of mild exercise diminished the alkali excretion temporarily. If the subject on arising walked quietly to the laboratory (one block) and worked there throughout the morning, the tide was practically obliterated. These deviations were not accompanied by a diminution in the output of urine. Increased acid excretion began about one and one-half hours after breakfasting immediately on waking and continued for an hour, after which the alkaline deviation began, the curve being steeper and rising somewhat higher than that of the control series. Increased excretion of acid after breakfast was seen in all experiments. When orange juice or small doses of sodium bicarbonate were taken late in the evening, there was a marked increase in the morning alkali excretion.

Antitoxin for Toxin of Clostridium Welchii in Blood After Peritonitis.—Bower and his associates believe that Clostridium welchii has an important part in spreading peritonitis of appendical origin. In ten apparently normal adults used as controls the incidence of antitoxin in the blood serum was zero, in nine patients convalescing or recovered from acute unperforated appendicitis the incidence of demonstrable antitoxin in the blood serum was 22.2 per cent, in fifteen patients with active or quiescent pelvic peritonitis the incidence of demonstrable antitoxin was 46.6 per cent and in twenty-eight patients suffering with or recovered from spreading peritonitis secondary to acute perforative appendicitis the incidence of demonstrable antitoxin in the blood serum was 69 per cent.

The authors have been using perfringens antitoxin in the treatment of cases of spreading peritonitis following perforative appendicitis with results which are encouraging and which will be reported later.

Erythrocyte Sedimentation and Anemia.—Bouton contends that the relative number of erythrocytes in the plasma has a negligible effect alone on their rate of settling. Some factors affecting the rate of erythrocyte settling which are listed indicate the present status of sedimentation as nonspecific and only partly understood. Attempts at "correction" of the sedimentation rate by compensating for anemia, and especially the use of "conversion charts," represent pseudoaccuracy and in large part invalidate the readings. The "unmodified" sedimentation curve is a valuable diagnostic aid when correlated with other laboratory and clinical data. Selected curves are reproduced to show that the sedimentation rate and the red cell count may fluctuate independently of each other and even move in opposite directions in the same individual, in the course of a pathologic process. If a patient with a low red count but otherwise essentially normal manifestations shows a definitely pathologic sedimentation curve, the true ailment has not been determined and is of a serious nature.

Primary Ureteral Neoplasms.—Rusche and Bacon report two cases of primary ureteral tumor. In the first patient there was rapid dilatation of the right renal pelvis. When the first pyeloureterograms were made, the pelvis appeared normal; it was remarkably dilated from back pressure due to the tumor a month later. There is only one pathognomonic sign of ureteral tumor, the demonstration of a filling defect in the ureter by a pyelo-ureterogram. The first pyelo-ureterograms failed to disclose a filling defect in the ureter, nor did an intravenous ureterogram help; but, by using a ureteral catheter of small caliber and withdrawing it a few centimeters at a time from the pelvis to the bladder and taking a series of roentgenograms on the way down, clear evidence of the filling defect was obtained. Papillomatosis recurred in the bladder following removal of the ureter at the ureterovesical junction. In the second case a positive diagnosis of ureteral tumor was made from the pyeloureterograms alone. There was no obstructive pathologic change above the tumor in this case. With these two cases there were 136 cases of primary ureteral neoplasms (forty benign and ninety-six malignant) supported by adequate histologic proof in the literature up to the end of 1936.

Bundle Branch Block.—From a review of literature, necropsy observations of sixteen cases of bundle branch block and of six cases of bundle branch block studied by means of serial sections through the conduction system, Yater concludes that bundle branch block is usually due to coronary arterial disease or to hypertension resulting in left ventricular strain and impaired nutrition of the endocardium and bundle branch. Bundle branch block is usually associated with bilateral bundle branch lesions, although one branch is usually more seriously affected than the other and probably usually determines the essential form of the electrocardiographic curves. "Right" bundle branch block is probably usually due to rheumatic arteritis or rheumatic myocarditis. "Left" bundle branch block is probably usually due to degenerative cardiovascular renal disease, meaning coronary arterial sclerosis or arterial hypertension or both. A bundle branch need not be entirely destroyed at any level in order to produce electrocardiographic alterations that may be designated "bundle branch" block. Increased amplitude of ventricular complexes is not essential to the electrocardiographic diagnosis of bundle branch block. Any increase of the QRS interval beyond 0.1 second may indicate lesions of the bundle branches.

- *Ménière's Disease: Study Based on Examinations Made Before and After an Intracranial Division of Vestibular Nerve. S. J. Crowe, Baltimore.—p. 1.
- Clinical and Experimental Results with Thorotrast. D. L. Reeves and R. M. Stuck, Montreal.—p. 37.
- Pathologic Physiology of Chronic Cardiac Decompensation. M. D. Altschule, Boston.—p. 75.

Ménière's Disease.—Crowe studied 117 patients seen at the Johns Hopkins Hospital during the last nine years. In twenty-three the disease was relatively mild and no immediate operation was indicated; they have been reexamined from time to time. In ninety-four patients the attacks were disabling and they came to the hospital to have their vestibular nerve divided. The author believes that stimulation of the vestibular end organs is the cause of the sudden, violent attacks of vertigo, the sensation of surrounding objects whirling and the temporary staggering gait in Ménière's disease. When the central vestibular pathways are irritated by a new growth, the dizziness and incoordination are constant, there is no sensation of objects spinning in a rotary direction, and the periods of freedom from all vestibular symptoms so characteristic of Ménière's disease are absent. In other words, Ménière's disease is a form of aural vertigo that involves the cochlea as well as the static labyrinth. Ménière's disease is a combination of vestibular and auditory disorders. The diagnosis is made largely on the description of the attacks of vertigo. Too much emphasis placed on special examinations (the audiometer, tuning fork and vestibular tests) may lead to confusion. Of the 117 patients, seventy-four were men and forty-three women. Only ten of seventy-one patients had a history of otitis media at any time, and only two had an infection of the accessory nasal sinuses when admitted to the

hospital. Vertigo, the symptom that disables these patients, is always cured by an intracranial division of the vestibular nerve. The deafness and tinnitus are only slightly less disturbing.

Congenital Megacolon Treated by Saline Irrigations.—Friedell suggests daily irrigations with physiologic solution of sodium chloride at 115 F. in the treatment of congenital megacolon. In three cases, treatment consisted of irrigation through a rectal instrument which permitted a controlled inflow and outflow. The treatment lasted from thirty to ninety minutes at first, depending on the response of the patient, but never less than twenty minutes. Several gallons of solution was used at one time. The solution was prepared at the bedside by dissolving the required amount of salt in a gallon of hot water. The irrigations were given slowly to avoid distention. In a few days the patients showed signs of improvement. Hurry or rough handling will frustrate all efforts and aggravate the condition. While in the three cases discussed normal intestinal function has been established, no claim can be made that all patients with megacolon can be cured. No damage should be done by trying this method first, and those ultimately requiring a sympathectomy will be better prepared by such irrigations.

Sulfanilamide in Gonorrhea in the Male.—Brunet and his associates used sulfanilamide as an adjuvant in the treatment of several hundred acute and chronic, anterior and complicated cases of gonorrhea in the male. Sulfanilamide has not yet proved to be a specific for gonorrhea in any stage of the disease, but they do find that its conservative use has been of benefit in

a number of cases. They recommend that not more than 40 grains (2.6 Gm.) be taken daily. They prescribe two 5 grain (0.3 Gm.) tablets and an equal amount of sodium bicarbonate, to be taken every three hours. Even this small amount causes unexpected symptoms in a number of patients. Larger doses should be withheld until the pharmacology of the drug has been more thoroughly studied and its action understood, for it is possible that its injudicious use may induce mortality in a disease which ordinarily should have none. Overenthusiastic manufacturers must not continue to impose on the credulity of the practitioner, and skeptical physicians should not minimize the value of the drug without sufficient trial. The place the compound will occupy in medical practice must depend on time and the unbiased sifting of divergent clinical experiences and opinions.

Cod Liver Oil Locally in Treatment of Ulcerative Colitis.—Manville devised a method of topical application of cod liver oil to the mucosa of the descending colon, sigmoid and rectum. The apparatus is composed of an ordinary paint gun as employed in the application of paint by the spray method. The only difference is that the nozzle is specially designed so that the tip will barely protrude beyond the end of a sigmoidoscope. The air pressure is adjusted by the use of an air pressure reduction gage so that it is barely sufficient to deliver a spray at the tip of the nozzle. The preliminary care of the patient is similar to that commonly employed for a proctoscopic or sigmoidoscopic examination with the exception that in addition a cleansing enema is used. The sigmoidoscope is inserted full length, the nozzle of the spray gun is then placed in posi-

tion and the pressure is released. The entire apparatus is slowly withdrawn, thus leaving a thin coat of cod liver oil applied directly to the mucosa. If necessary an oil (15 cc.) retention enema may be used at night. This method of treatment of ulcerative colitis substantiates the results given by Spiegel and the technic described is believed to be better. The few patients who have been treated have been distinctly benefited.

Ringworm and Moniliasis.—Hopkins points out that 6,515 patients were admitted to the Department for Skin Diseases and Syphilis of the Vanderbilt Clinic in 1936 and that a diagnosis of some form of fungous infection of the skin was made in 442 cases. The common superficial fungous infections include two large groups—ringworm and moniliasis—and also a few other types. Ringworm infections are really two diseases: (1) ringworm of the scalp and glabrous skin, which is caused in the main by one group of fungi (the microspora, the favus fungus and the Endothrices) and (2) ringworm of the hands, feet, nails and groin, which is caused by another group. The prevention of contagion in each type of infection presents a distinct problem. It is difficult to predict from the appearance of a scalp lesion the type of fungus that will be recovered. On the hands and feet, however, the most varied types of lesion are caused by the same species. Different strains of one species vary greatly in virulence. Variations in the clinical picture seem to depend more on variations in reactivity of the patients than in virulence of the strains. Accurate diagnosis requires careful laboratory examination.

Ultraviolet Rays in Treatment of Erysipelas.—Schunk treated thirty-two cases of erysipelas with ultraviolet radiation. The ages of the patients varied from 1 month to 71 years. Thirteen were males and nineteen females. In twenty-eight the lesion was on the face or ear, in three on the leg and in one on the hand. No treatment other than ultraviolet radiation was used on any patient except one who received one dose of erysipelas streptococcus antitoxin. Thirty patients remained ambulatory and two were confined to bed. Definite improvement began within twenty-four hours after the first treatment in twenty-seven cases. The remaining five began to improve after the second or third treatment. Morbidity ranged from one to ten days with the exception of one patient, 71 years of age, who developed multiple abscesses in the subcutaneous tissues of his leg following subsidence of his erysipelas. There have been no deaths. The machine used is a mercury arc air cooled type which delivers an erythema dose in about one minute at a distance of 20 inches. The best response was obtained if an exposure of fifteen minutes at 20 inches was given at the time of the first visit. If the patient's skin was already tanned from being in the sunlight, the exposure was increased to twenty minutes. In infants or in people with a fair complexion the original dose was correspondingly reduced. Succeeding exposures were increased according to the amount of erythema obtained. From one to three treatments usually effected a cure if the dosage was sufficient. The entire lesion and a wide unlimited margin of normal skin were always exposed. Three patients had erysipelas more than once. The recurrences rapidly subsided under ultraviolet therapy, as did the original lesions.

Pneumoperitoneum in Perforations of Gastrointestinal Tract.—Paine and Rigler made observations on thirteen patients incidental to the production of a diagnostic pneumoperitoneum. Similar observations were made on five cadavers shortly after death in which it was shown that at times as small a quantity of gas as 5 cc. in the right subphrenic space can be demonstrated on a roentgenogram and 10 cc. can be seen regularly without difficulty. There have been sixty-two proved cases of perforation of the stomach, duodenum, small intestine and colon treated at the University of Minnesota Hospitals between 1927 and 1937. Forty-seven of the patients were given x-ray examinations, and gas outside the gastrointestinal tract was observed in 78.8 per cent. In thirty-eight cases of perforation of the stomach or duodenum, free gas was observed in twenty-eight (73.7 per cent). The reasons why gas is not seen in every case probably include (1) adhesions in the right upper quadrant of the abdomen, (2) location of the perforation below the fluid level of the fluid in the viscus, (3) absence of gas in the viscus at the time of perforation, (4) temporary plugging of the perforation with gastric or intestinal contents until the perforation is walled off, (5) prolapse of redundant mucosa into the perforation blocking the exit of gas and (6) technical failures in the x-ray examination. X-ray examination in the left lateral decubitus position was found to be of value in establishing the diagnosis of spontaneous pneumoperitoneum. If pneumoperitoneum is observed at all on the roentgenogram, it will be seen between the right dome of the diaphragm and the liver in 90 per cent of the cases.

*Pemphigus Neonatorum (Bullous Contagious Staphylococcal Impetigo of the Newly Born): Account of Two Epidemics and Review of Literature. F. D. Hart.—p. 118.

Pemphigus Neonatorum.—Hart describes two epidemics of pemphigus of the newborn. *Staphylococcus aureus* was found in all cases, while attempts to grow streptococci failed. The effusion from the infected areas grew only *Staphylococcus albus* in two cases. One epidemic appeared to be started by an infant with rhinorrhea, from which a profuse pure growth of *Staphylococcus aureus* was obtained. The origin of the second was obscure but followed a mastitis in the child's mother. This also yielded a pure growth of *Staphylococcus aureus*. The organisms appeared to be indistinguishable from the usual strains of *Staphylococcus aureus*. Two deaths occurred at the close of the second epidemic from fulminating staphylococcal pneumonia. When the first case occurs, the ward, laundries and nurses should be thoroughly investigated, and the wards and laundries painted if necessary. The lesion is essentially bullous and the contents of the bullae are highly contagious. All premature babies and babies less than 6 days old are in grave danger in an epidemic. The lesions usually cause no systemic upset unless large and spreading and of an exfoliative type. No particular treatment seemed appreciably better than any other, though it was felt that ultraviolet radiation might have helped. Mercuriochrome, potassium permanganate baths, dusting powders and the like seemed of equal value. Provided the blister was snipped, the contents wiped up and the part kept from coming into contact with other parts, the natural tendency was to get well.

Intradermal Test for Vitamin C Deficiency.—Portnoy and Wilkinson employed the cutaneous test used by Rotter for estimation of the vitamin C nutrition of the body. This test depended on the fact that 2:6-dichlorophenolindophenol is decolorized by

the tissues at a rate depending on the content of cevitamic acid. In "saturated" cases the dye disappears in less than five minutes, in "normal" cases in from five to ten minutes, and in "deficient" cases the dye takes longer than ten minutes for decolorization. Tests were made on 103 patients under observation for other purposes, and seventeen of these were reexamined after complete saturation with the acid. Conclusions are not attempted, but it is seen that a decolorization time greater than ten minutes apparently parallels a deficiency of vitamin C. This does not necessarily mean that the cutaneous test is a direct measure of the cevitamic acid content of the tissues, since other reducing substances, such as glutathione, will also cause a reduction of the dye. Nevertheless Rotter's test may furnish a useful rapid clinical test for vitamin C subnutrition and is worth further study.

Prontosil in Treatment of Oriental Plague.—Carman tried prontosil (the disodium salt of 4-sulfamidophenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3', 6'-disulfonic acid) in the treatment of six cases of bubonic plague. The strain of *Bacillus pestis* that has been responsible for the cases which have occurred during 1937 has manifested a high degree of virulence, since none of the first nine patients recovered. Of six patients subsequently admitted, three recovered. Morning and evening injections of from 2.5 to 5 cc. of prontosil were given. The evidence in favor of the assumption that prontosil is of value in the treatment of bubonic plague is sufficient to warrant a more extended trial.

Uremia After Hemorrhage.—Bookless encountered thirteen cases in which a raised blood urea followed hematemesis and melena. In ten of them hemorrhage presumably arose from simple peptic ulcers; increasing pallor, attacks of faintness or melena often preceded the actual hematemesis. Every patient vomited blood and either fainted or collapsed immediately. On admission the hemoglobin varied between 30 and 80 per cent. Most of the patients had constipation for a week and any motions passed contained obvious altered blood; occult blood persisted in the stools for about three weeks. Hematemesis recurred in only one patient, and eight out of the ten recovered. In the other three patients hemorrhage was complicated by obstruction; vomiting recurred, anemia and dehydration increased and in spite of temporary phases of recovery the condition of the patients steadily deteriorated. The author believes that uremia after hematemesis is mainly due to increased breakdown of tissue protein, a process rapidly increased by sudden loss of blood and later maintained or further accelerated by dehydration. Wasting and dehydration are commonly associated. Experimentally pure dehydration may cause wasting. Adequate nutrition in the early stages mitigates secondary hemorrhagic shock without apparently restarting hemorrhage.

Bone Formation in the Scala Tympani in Otosclerosis.—Nager and Fraser encountered bone formation in the scala tympani in only six petrous bones out of sixty-two cases of otosclerosis. Analysis of these cases indicates that the extent of the disease of the bone in the labyrinthine capsule of all these patients was large and not circumscribed but diffuse and including both windows. The bone marrow contained many dilated blood vessels, newly formed connective tissue and numerous osteoclasts. These patients were almost totally deaf, which condition is easily explained by the obliteration of both windows. The scala tympani was almost filled up in the more advanced cases. With the exception of one case, the lowest end of the scala tympani was filled up, including the cochlear aqueduct. In general the inner ear of these petrous bones did not show distinct signs of old inflammation, with the exception of a darker staining of endolabyrinthine fluids. They cannot accept the idea of a former labyrinth infection as a cause of these alterations but are inclined to believe that the otosclerotic process in the labyrinthine wall produces alteration or irritation of the endosteal layer and perilymphatic space which leads to circumscribed fibrous and bony production in the scala tympani. The otosclerotic process will penetrate even this newly formed bone. Such formation of bone in the inner ear has been found only in otosclerotic diseases of the labyrinthine capsule, whereas all other disorders of bone do not lead to these alterations.

Effect of Anterior Pituitary Extracts on Liver Fat.

Best and Campbell find that in fasting animals the anterior pituitary preparation causes a much greater increase in liver fat in guinea pigs and mice than in rats. Fasting alone produces a pronounced increase in liver fat in guinea pigs and mice. The amount of fat in the liver of the rat is frequently decreased by short periods of fasting. Female guinea pigs exhibit a greater increase in liver fat than males during the administration of the anterior pituitary preparation. The fat which accumulates in the liver of the fasting rat after injections of anterior pituitary rapidly disappears when the injections are stopped. Despite continued daily injections of the preparation to fasting rats or guinea pigs, a decrease in liver fat occurs after several days. In fasting rats or guinea pigs the preparation causes a fall in body fat. The preparation produces an increase in liver weight, which is due chiefly to deposition of fat and water. A slight increase in nonfatty solid material also occurs.

Prognosis in Malignant Disease of Testicle.—Payne bases his remarks on thirty-eight cases in which malignant disease of the testicle was treated by means of orchidectomy at St. Bartholomew's Hospital during a period of thirteen years. The diagnosis was confirmed pathologically. The orchidectomy was a local operation, and no patient was subjected to the radical operation. In addition to the orchidectomy, other treatment was carried out in some of the cases, including the excision of inguinal glands, the insertion of radon seeds to the abdominal glands and roentgen therapy. Of the thirty-eight all but four patients have been traced. In fifteen (46.9 per cent) of a possible thirty-two cases there was a cure rate of five years or more in a disease commonly regarded as almost uniformly fatal.

Comparison of Insulin and Metrazol in Schizophrenia.

—Strecker points out that up to last May, when an international conference on insulin and metrazol therapy was held in Switzerland, more than 2,000 patients had been treated with insulin hypoglycemia all over the world, and more than 600 with metrazol convulsions. The methods are not equally effective with all types of schizophrenia. Hebephrenia and dementia simplex both give relatively poor response to either method; in the other types the order of improvement with metrazol is generally inversely that with insulin. For example, catatonic excitement and paranoid types are more responsive to insulin, whereas stupor responds better to metrazol. This is of practical importance and shows the value of combining or of alternating the two methods. Angyal and Gyárfás, by supplementing the treatment of those refractory to metrazol by a period of insulin, found their remission rate increased from 44 to 63 per cent. The insulin and metrazol cases taken together (irrespective of their duration) show complete or incomplete remission in 40 and 37 per cent respectively, while a general survey of spontaneous remissions shows that, of a total of 2,460 patients, 236 per cent were reported at home well or improved. An economic fact of great importance is that the average stay in the hospital is much reduced both by insulin and metrazol treatment and recovery after these methods, as judged by insight and contact obtainable, is more complete than in spontaneous remission.

Source of Infection in Puerperal Sepsis.—Durie believes that the chief danger is probably the throat carrier, for the human throat seems to be the natural habitat of *Streptococcus pyogenes*. It is therefore imperative to examine throat and nose swabs from all attendants who acquire tonsillitis or other respiratory infection or who have been in contact with a case of puerperal sepsis. Only one third of the hemolytic streptococci

found in the human throat are pathogenic. When the hemolytic group A streptococcus is isolated from a throat carrier by the precipitin test, that carrier is regarded as potentially dangerous. But the precipitin test does not provide a means of identifying a carrier as the source of infection in any particular case; it only shows that such a carrier is a possible source of infection. The source of infection in every case of puerperal sepsis should be determined. This identification of the source of infection is made possible by the existence of Griffith's types of hemolytic streptococci by the method of agglutination and agglutinin absorption. There are at least twenty-seven distinct types of hemolytic streptococci within group A. The hemolytic streptococcus is just as dangerous to the newborn as to the puerperal patient. The route of infection appears to be sometimes the respiratory tract.

Thiamin Chloride in Treatment of Neuritis.—Stevenson gave intramuscular injections of thiamin chloride into alternate upper arms, in an uninterrupted course, to thirty-five patients with resistant neuritis, sciatica and nervous debility when usual measures failed to give relief. The injections used were 1 cc. in bulk and contained either 1 or 2 mg., being equal to a strength of 500 and 1,000 international units. Six patients with sciatica and eight with neuritis were cured and six with sciatica, four with neuritis and three with nervous debility were greatly improved. As it is uncommon to find a pure neuritis without arthritis or fibrositis, the institution of some form of electrotherapy with or without massage is indicated.

Vitamin C Content of Blood Plasma in Children.—Chu and Sung believe that the determination of the vitamin C content of the blood plasma is a useful method of ascertaining the state of nutrition relative to vitamin C. It is more reliable than the estimation of the skin capillary resistance and more practicable than the study of urinary response to a test dose of the vitamin. By correlating the vitamin C content of the plasma with the type of urinary response to repeated daily test doses of the vitamin in eight cases, it was found that 0.85 mg. or more of vitamin C per hundred cubic centimeters of plasma correspond to the "relative saturation" of the body with the vitamin, that values between 0.5 and 0.8 mg. represent a range of "presaturation," and that any values below 0.4 mg. may be considered "deficient" with regard to vitamin C metabolism. All the breast-fed infants examined had a concentration of more

than 0.5 mg. of vitamin C per hundred cubic centimeters of plasma, while the infants who were artificially fed with slight or no addition of cabbage water had values ranging from 0.168 to 0.342 mg. When a considerable amount of orange juice or cevitamic acid was administered orally to the artificially fed infants who were not acutely ill, an increase of vitamin C in the plasma was invariably demonstrated. The vitamin C content of the plasma remained at a low level during the active stage of acute bacillary dysentery, even when antiscorbutic fruit juices had been given in a liberal amount. Parenteral administration of vitamin C is indicated for such patients. In cases of kala-azar, noma seems to be associated with a very low vitamin C level in the plasma. In the case of active tuberculosis the vitamin C content of the plasma was found to be invariably low, even when breast milk or orange juice had been included in the diet.

Staphylococic Bacteremia in Children.—Between 1921 and 1936 Wu encountered forty-three cases of staphylococic bacteremia in Chinese children up to 12 years of age in the Peiping Union Medical College Hospital. He emphasizes that staphylococic bacteremia is neither a rare condition nor always innocuous. The mortality for the whole group was 86 per cent and that for the children less than 2 years of age was 100 per cent, excluding two patients who left the hospital unimproved. About 69.8 per cent of the patients were up to 2 years of age. The infection could usually be traced to some sort of cutaneous lesions in the summer and respiratory diseases in the winter months. Cutaneous infections resulting from superficial abrasions or punctures for diagnostic and therapeutic purposes may at times lead to a fatal outcome. Although specific therapy is not available, energetic treatment along general lines does at times give gratifying results. A boy, 11 years old, with persistent bacteremia, recurrent osteomyelitis and arthritis, pneumonia with empyema and suppurative pericarditis, got well in about five months as a result of prompt and adequate surgical intervention of the local conditions and repeated blood transfusions. The ratio in the present series was 1.66 boys to one girl.

*Tubal Permeability in Adnexitis. C. Daniel, D. Mavrodin and A. Wanoff.—p. 15.

Tubal Permeability in Adnexitis.—Daniel and his associates review the literature on the permeability of the uterine tubes in adnexitis and report their investigations. Permeability of the uterine tubes in adnexitis is more frequent than is generally believed, amounting to 43.2 per cent of the cases. In cases studied by the authors, bilateral permeability was detected in 13.5 per cent and unilateral permeability in 24.3 per cent. Insufflation of the uterine tubes rendered them permeable in the course of insufflation in 5.4 per cent of the cases of adnexitis. In two cases of pelvic cellulitis, after delivery and abortion, the permeability of the uterine tubes indicated that the inflammation of the cellular tissues left the tube unharmed and consequently did not predispose to sterility, as occurs in inflammations of the uterotubal tract. In their observations in thirty-nine cases, it appeared to the authors that tubal insufflation, correctly and carefully employed, is a harmless method, which does not produce accidents even in acute and subacute forms of adnexitis. The permeability of the tube does not signify everything in the diagnosis of sterility; it also indicates the condition of the tubal wall, a fact which one of the authors studied on another occasion; nevertheless, on the basis of their observations they propose the systematic application of tubal insufflation, together with other methods of functional exploration, in all cases of adnexitis in order to recognize the possibility of fecundation.

The Bovine Bacillus and Tuberculous Meningitis.—Lesné and Saenz report the results of investigations on tuberculous meningitis in 155 children who had not been subjected to BCG vaccination at birth. It was necessary to eliminate eleven cases in which the culture of the cerebrospinal fluid was negative and in which the evolution of the disease diverted the diagnosis of tuberculous meningitis to that of curable serous or lymphocytic meningitis. The inoculation of the remaining 144 specimens of cerebrospinal fluid into the medium of Loewenstein always resulted in the culture of tubercle bacilli. In 135 of the cases the bacilli were of the human type and in nine of the bovine type. In the 135 cases with the human type, the appearance of the colonies in the Loewenstein medium required from eleven to twenty-nine days; the colonies were reddish, yellowish, dry, from 4 to 12 mm. in diameter, abundant and eugonic. On the other hand, in the cases in which the bovine bacillus was found, the colonies appeared extremely late, from thirty to seventy-two days being required. Moreover, these colonies were small, not pigmented, humid and dysgonic. The intravenous injection into rabbits of the strains of bovine bacilli confirmed the cultural diagnosis. All the animals died after from fifty-five to sixty-one days. The authors stress the great sensitivity of the Loewenstein medium and the fact that it permits differentiation between the human and bovine types of tubercle bacilli before the animal test is made. The bovine strains that were isolated in the aforementioned cases showed the characteristic properties inherent in this type of bacillus. No atypical or attenuated strains were found. By successive cultures on glycerinated potato mediums, the majority of the bovine strains, originally appearing in dysgonic colonies, were transferred into eugonic colonies. It was found that for guinea pigs the virulence of the bovine strains isolated from the children with tuberculous

meningitis was greater than that of the human strains. Discussing the etiologic aspects, the authors stress the following points: The age of the children attacked by the bovine bacillus varied between 18 months and 6 years, whereas the age of the children with the human strains extended to 15 years. Nearly all the children who were infected with the bovine bacillus were either raised or had lived for longer periods in rural regions. Indications for familial infections were lacking in the majority of children infected with the bovine strain. Moreover, in all the cases of meningitis with the bovine bacillus, the source of contamination was raw cow's milk, which had been ingested for long periods. The circumstances were quite different in the children in whom the tuberculous meningitis was caused by the human type of the tubercle bacillus. Of these, 92 per cent lived in or near Paris and only 3.17 per cent lived in rural districts. The majority had been nursed at the breast or were fed with sterilized cow's milk. Human contagion was found in the majority of cases. The authors conclude from these investigations that in France the bovine type of tubercle bacillus plays a much smaller part in the etiology of tuberculous meningitis than is the case in some other European countries; for instance, in England and Denmark (from 30 to 42 per cent). Nevertheless its etiologic importance is not negligible and necessitates prophylactic measures, such as the elimination of tuberculosis among cattle, prohibition of the feeding of raw milk to children and strictly controlled pasteurization.

Copper Sulfate in Treatment of Anemia.—Canelli says that for years he has used copper sulfate in the treatment of true anemias and of chlorosis and has obtained favorable, rapid and lasting results. He thinks that this little known therapy should be placed beside the better known treatments with iron, arsenic, manganese or liver, the more so since it can be employed in almost all ages. The oral mode of application is simple and the small volume, which is not disagreeable to the taste, is well tolerated by the gastrointestinal tract. Occasionally the effects of copper therapy surpass those of the customary anti-anemic measures. The copper stimulates the regeneration of the blood cells, increases the number of erythrocytes, influences the synthesis of hemoglobin and increases the hemoglobin content. Nevertheless the superior results should not lead to over-evaluation, because copper treatment also fails quite often. It can be used as an auxiliary measure with other antianemic medicaments. The author employs copper sulfate in a 1 per cent aqueous solution with various bases. He administers it immediately before the two principal meals, in doses of from 10 to 20 drops, for periods of ten days with intercalated periods of rest. The author found the copper treatment especially valuable in secondary anemias caused by rickets, inadequate diets, acute or subacute infectious diseases, intestinal intoxication, tuberculosis, syphilis, chronic renal lesions, hemorrhages and so on, also in chlorosis.

Osmotic Resistance of Erythrocytes in Typhoid.—Sciclounoff and Roch studied the resistance of the blood cells in patients with typhoid. They determined at the same time the coagulation time, the bleeding time and the retraction of the blood clot. They made their studies on four siblings aged between 13 and 18 years and made the following observations: 1. The resistance of the blood cells underwent a considerable diminution in all the patients; this reduction took place between the third and seventh weeks of the disease and involved the minimal as well as the maximal resistance. In three of the patients the reduction in the minimal resistance was preceded by a considerable augmentation. 2. Destruction involving approximately one fifth of the erythrocytes and of the hemoglobin was found to run parallel with the diminution in the resistance of the blood corpuscles. 3. The lowering of the resistance and the destruction were accompanied by a discharge of

urobilin and of urobilinogen in the urine. 4. In the measure that the cellular resistance diminished, the coagulation was prolonged. However, there was no considerable variation in the bleeding time and in the time required for the retraction of the blood clot. 5. The sedimentation speed of the erythrocytes was moderately augmented from the third week of the disease. 6. The described observations indicate that a fragility of the erythrocytes plays a part. This loss in resistance is probably provoked by the eberthian toxins. Without being able to prove it, the authors suppose that it is a toxicosis of the reticulo-endothelial system in general and of the bone marrow in particular. 7. The authors think that the administration of lipoids or of phosphatides may be helpful in these patients, because of the favorable action of these bodies on the resistance of the blood cells and on the reticulo-endothelial system in general.

Prosthesis of Common Bile Duct by Direct Implantation of Rubber Tube in Duodenum. F. Virgilio.—p. 172.

Lateroterminal Anastomosis of Nerves.—Gatta experimented on young rabbits. In the first group of animals the end of the peripheral segment of the sectioned peroneal nerve was introduced into the normal tibial nerve and fixed there by a suture. In the second group of animals 3 or 4 mm. of the scarified end of the peripheral segment of the sectioned peroneal nerve was placed in contact with a longitudinal incision in the normal tibial nerve and fixed there by two stitches, 3 or 4 mm. apart. The anastomosis was performed immediately after sectioning of the peroneal nerves in the first and second groups of the experimental animals. In the third group the anastomosis was done by the technic of side by side contact of the nerves, which was used in the animals in the second group, but it was done one month after section of the peroneal nerve. In all the animals the nervous stimulations of the central segment of the sectioned nerve were deviated away from the peripheral segment. The author concludes that the fibers of a sectioned motor nerve regenerate themselves by the lateroterminal anastomosis to a normal nerve which has motor fibers. Regenerated nervous fibers originate at the anastomosing segment of the normal nerve and progress peripherally to the anastomosed cut nerve. Regeneration induces complete reestablishment of nervous supply in both anastomosing and anastomosed nerves. It is followed by reappearance of functions in the previously denervated territory. Early in the experiment there is a slight muscular hypotrophy. The anastomosis by side by side contact of the nerves gives better results than the introduction of the end of the paralyzed segment of the nerve into a normal nerve.

Chronic Hilar-Mediastinal Lymphopathy in Children. D. Eller.—p. 118.

Bromine in Blood of Normal Children.—Gatto says that it is obvious after reviewing the literature that the investigations on the amount and physiologic importance of bromine in the blood and in certain fluids of the body have given conflicting results up to the present. The blood of infants, immediately after birth, contains bromine which shows placental origin. Bromine is present also in the blood of the umbilical cord. After birth, infants receive bromine in mother's milk or in artificial feeding. The author performed determinations of the amount of bromine in the blood and the cerebrospinal fluid of normal infants and children. He resorted to Kirchhof's method, which is a modification of Indovina's, in which 2 cc. of a 5 per cent sodium paratoluenesulfonchloranide (chloramine) is used, instead of the same quantity of water charged with chlorine, which is used in the original method. The author concludes that the amount of bromine in the blood of normal infants and children varies between 519 and 958 micrograms for each

hundred cubic centimeters of blood. Variations of the amount of bromine in the blood, within normal figures, are more restricted in the blood of infants who are fed human milk than in those of infants who are fed artificial or mixed food and of children. The amount of bromine in the blood depends on the amount ingested with food. Infants who are fed human milk ingest a fixed amount of bromine in the milk daily. In artificial or mixed feeding and in the diet of children the amount of bromine in the food is not the same every day. The ratio of bromine in the erythrocytes and in the plasma varies between 0.65 and 0.75. Bromine in the blood accumulates in the erythrocytes with a greater tendency than chlorine. The amount of bromine in the cerebrospinal fluid varies between 95 and 320 micrograms for each hundred cubic centimeters of the fluid. It is greater in the cerebrospinal fluid of infants than in that of children. This is due to the fact that the barrier of the central nervous system has a lower threshold to the passage of bromine from the blood during early life than later on, as the children advance in age.

Useful Modification of Hagedorn-Jensen Micromethod for Determination of Glycemia. A. Midana.—p. 237.

Treatment of Multiple Sclerosis.—In forty cases of multiple sclerosis Tanfani resorted to Boschi's treatment, which consists in the production of aseptic meningitis followed by intramuscular injections of the patient's own blood and cerebrospinal fluid. Aseptic meningitis is produced by injecting from 2 to 5 cc. of double distilled water in the spinal canal. The patient's own blood, in small progressive amounts not specified by the author, is injected six or seven hours later. The amount of cerebrospinal fluid is 5 cc. for each injection. The total number of treatments varies from two to four. Intervals of two or three weeks are allowed to pass between the treatments. The author's cases were grave and of long duration. Recovery (except for the organic defects) took place in three cases, great improvement in six cases and moderate improvement in thirteen cases. The treatment failed in eighteen cases. The reaction consists of headache, vomiting, pain in the extremities and vertebral column, flexor spasms, fever between 39 and 40 C. and intense lymphocytosis of the cerebrospinal fluid. The benefits of the treatment are evident after the second or third injection in the majority of cases. The best results of the treatment are attained in patients who show an intense meningeal reaction and no tendency to spontaneous reactions, especially if the disease is of the cerebellopyramidal type and has lasted for less than six years. The satisfactory results of the treatment cannot be mistaken for spontaneous reactions.

Clinical Pathogenic and Surgical Study of Three Cases of Intervescal-Prostatic Diaphragm Secondary to Transvesical Prostatectomy. D. Torre.—p. 143.

Postoperative Hepatorenal Syndromes.—Culmone states that the acute hepatonephritis which frequently follows surgical procedures, especially on the abdomen, the liver and the biliary tract, is a form of toxic hepatonephritis by which the metabolisms of proteins, sugars, chlorides and water are disturbed and the acid-base equilibrium is destroyed. The disorder may develop regardless of the type of anesthesia used. It is due to the presence of latent chronic insufficiency of the liver and the kidney in association with constitutional intolerance of the structures for certain toxic substances. The presence of latent hepatorenal insufficiency and constitutional intolerance explains the benign or fatal evolution of hepatic and liver insufficiency which complicates operations on the abdomen. In the presence of the pathogenic factors mentioned, toxic anesthetic and cytolytic products induce irreversible lesions in the parenchyma of

the liver and the kidney. The lesions form organic autolysates of great toxicity, which have reciprocal tropism and an aggravating effect on the lesions of either structure. Grave biochemical and humoral changes, which are incompatible with the preservation of the patient's life, follow. Myocardial and circulatory disturbances, coma and vasomotor collapse are terminal symptoms. Clinical preoperative examination of the structures does not reveal latent chronic, hepatic and renal insufficiency. Constitutional intolerance, if it is present, is common to the liver and the kidney, which have a common phylogenetic origin. The author's statements are based on a review of the literature and on the clinical study of seven cases which he reports.

Microscopic Changes from Intra-Arterial Injections of Gentian Violet.—Repetto experimented on rabbits that had been given an intra-arterial injection of 0.25 cc. of a hydro-alcoholic solution. The solution was prepared with 1 Gm. of gentian violet, 10 Gm. of alcohol and 100 cc. of water. The injection was done in the femoral artery, which was examined within two and twelve days after. In all cases the injection induced grave alterations in the limb. There were intense edema, cutaneous ecchymoses and large zones of deep cutaneous necrosis. Microscopic study revealed peeling of the endothelium of the arteries, intense edema, leukocytic infiltration, dilatation of the vessels of the skin and of the subcutaneous and muscular tissues, diffuse hemorrhages, necrosis of the epidermis and deeper layers of the skin and degeneration of the muscular fibers. The author warns against the use of intra-arterial injections of gentian violet in the treatment of infections of the limbs.

*Triangular Parapericardial Roentgen Shadow. A. Trimani.—p. 512.

Triangular Parapericardial Roentgen Shadow.—Trimani found the parapericardial triangular shadow at the left lower arch of the roentgen silhouette of the heart in fifty-seven of 3,568 teleroentgenograms and 400 orthodiagrams which he studied. The author states that the shadow is due to the presence of a ligament or band which joins the juxta-apical portion of the fibrous pericardium to the left hemidiaphragm. Polycyclic conglomerates of fat tissues may accumulate at the level of the left diaphragmatic-pericardial angle. In rare cases the fat tissues may be a coadjuvant factor for the formation of the shadow, which may originate in the presence of fat tissues only in exceptionally rare cases. In such cases the external edges of the shadow are evanescent and irregular. The triangular parapericardial shadow may be present in the roentgen silhouette of the heart of patients who are suffering from cardiovascular diseases, especially sclerosis and thrombosis of the coronary arteries. It may be present rarely in the roentgen silhouette of patients with diseases other than cardiovascular and in the silhouette of normal hearts. It appears in persons over 40 years of age, thin or with diminished body weight. It has never been found in the silhouette of the heart of children or of patients suffering from heart diseases with enlargement of the heart. The appearance of the shadow depends on the position of the diaphragm and the presence or absence of enlargement of the heart. A low position of the diaphragm favors the appearance of the shadow, whereas the enlargement of the heart prevents it.

Differential Diagnosis of Epilepsy.—Scheid directs attention to the differentiation between genuine epilepsy and attacks of convulsions that develop as the result of anatomic lesions of the brain. Examination of the cerebrospinal fluid is important in this differentiation because the psychic changes may not be

clear and the neurologic symptoms are often negative in symptomatic epilepsy. The author tries to show what diagnostic conclusions can be drawn from the cerebrospinal fluid. Of sixty epileptic patients, fifty-four had normal cerebrospinal fluid. In only six patients, or 10 per cent, did the cerebrospinal fluid show pathologic aspects. In three cases the protein content was increased but there were no pathologic colloid curves. Increase in the number of cells without pathologic colloid curves was also observed in some cases of genuine epilepsy. This manifestation proved to be the result of an attack in most of the cases. Pathologic colloid curves suggest the symptomatic nature of the attacks. The colloid curves are never pathologic in cases of genuine epilepsy but they are in about half of the cases of symptomatic epilepsy.

*Atypical Reactions of Skin to Treatment with Borderline Rays. F. Kalz.—p. 377.

Short Wave Treatment of Actinomycosis.—Dieker points out that Liebesny, after the accidental discovery of the favorable effect of short waves on cutaneous actinomycosis, employed the short wave therapy in seven other cases of cutaneous actinomycosis and obtained favorable results in six out of eight cases. Dieker employed short waves (6 meters) unintentionally in a case of primary actinomycosis of the lungs and pleura. The short wave treatment was employed on the basis of the diagnosis of an encapsulated pleural empyema. Later, however, it was discovered that the process was an actinomycosis. When the short wave treatments failed to produce the expected results, the patient was subjected to an operation which definitely established the diagnosis of actinomycosis. Although the operation produced temporary improvement, the patient finally died. In the final evaluation of this case the author debates whether the unfavorable outcome was the direct result of the short wave treatment or of the inadequate defense powers of the organism. In view of the extremely poor general condition of the patient, the author is inclined to accept the second possibility and thinks that, since there is no other treatment which holds out a better promise of success in this form of actinomycosis than does short wave treatment, it might be tried again in cases of this type, particularly if they come up for treatment at an earlier stage than did the reported one.

Atypical Reactions of Skin to Borderline Rays.—Kalz describes two cases of abnormal reaction of the skin to irradiation with borderline rays. The first patient, aged 35, for two years had a mild eczema on both cheeks and on the forehead which proved refractory to treatment with ointments. In order to avoid the formation of an erythema, the author applied the borderline rays in fractionated doses. He gave eight irradiations of 100 roentgens each at three day intervals. After these irradiations an intensive erythema developed, which however did not involve the irradiated fields uniformly but rather appeared in areas with jagged outlines. On superficial observation they resembled a naevus flammeus. The erythema gave way to a rapidly disappearing pigmentation. In view of the fact that the outlines of the erythema did not coincide with the fields of irradiation, the author assumes the existence of a hypersensitivity. However, the sensitivity tests revealed no abnormality. Nevertheless, this case proves that there are patients in whom otherwise harmless doses may result in undesirable skin reactions. The second patient, a woman aged 34, was severely affected with acne vulgaris. Local treatments, courses of yeast and endocrine injections were used without success. Under the influence of fractionated treatment with borderline rays (9 times 150 roentgens at three day intervals) the acne pustules healed, but eight days after cessation of the irradiations a slight erythema devel-

oped and shortly afterward small, light red nodules appeared which persisted unchanged for about three weeks. After they had existed for about four weeks, small depressions became noticeable in the center of the nodules and magnification disclosed small telangiectasis. After two months the lesions were cured, leaving central scars and pigmentations. An irradiation impairment with such clinical aspects has not been reported heretofore. However, in view of the fact that the disorder developed together with the irradiation erythema and was restricted to the irradiated fields, it must be assumed that it was at least provoked by the irradiation.

- Isolated Occurrence of Laryngeal Tuberculosis. Maria-Therese Charlier.—p. 242.

Immunity and Allergy in Tuberculosis.—Nagel describes experiments conducted to detect relations between allergy and immunity. In the first series, eighty guinea pigs with severe tuberculosis and a number of controls were given intravenous injections of varying doses of virulent and killed tubercle and colon bacilli. A comparison of the organs of the animals with the severe tuberculous-fibrous changes with those of the control animals revealed no hyperergic-allergic reactions. To be sure, shock often followed by death was observed in the tuberculous animals that were treated with large doses. The necropsy of these animals disclosed severe parenchymatous hemorrhages in the organs and inflation of the still existing pulmonary tissues. The author thinks that these shock effects may be the result of suddenly increased toxic actions on a sympathetic which had become hyperirritable as the result of the tuberculous infection. This irritability can be increased also by colon bacilli. In the second series of experiments, twenty-three animals were given a preliminary treatment with a strain of bacilli of low virulence. After forty days these animals and a number of controls were given intravenous injections of a mixed vaccine containing highly virulent living and killed bacteria. In some of the experiments epinephrine was added in order to influence possible allergic-hyperergic reactions. The animals were killed after a varying number of days. In comparison with the controls, the animals having received the preliminary treatment showed a hardly noticeable increase in the general reaction. In the immunized animals, the development of the tuberculosis was noticeably retarded. In the third series of animals the author investigated the possible effect of local or general anesthesia on the development of hyperergic-allergic reactions. It was found that the anesthesia exerted no noticeable influence on the tissue reactions. Since hyperergic-allergic reactions were virtually absent, the author concludes from his observations that allergy and immunity represent two entirely different phenomena.

Open Tuberculosis in Children.—Ellinghaus presents a statistical report of eighty-two cases of open pulmonary tuberculosis in children that were treated at a sanatorium during the years 1928 to 1935. There were twenty-four boys and fifty-eight girls. Of the total number, forty-eight (58.5 per cent) had died by May 1, 1937; in twelve (14.6 per cent) the pulmonary process had become exacerbated; improvement or arrest had been obtained in twenty-one (25.6 per cent). Of the twenty-four boys, eleven (45.8 per cent) died; of the fifty-eight girls, thirty-seven (63.7 per cent) died. Thus the boys seem to have a more favorable prognosis than the girls. The author points out that his statistics show great similarity to those presented by Klare about open pulmonary tuberculosis in children and young persons, except that, according to Klare's figures, there is no essential difference in the prognosis as regards the two sexes. Klare, like Ellinghaus, observed a higher incidence of open pulmonary tuberculosis in girls than in boys. The author says that for children too the most promising procedure is collapse therapy, especially unilateral and bilateral pneumothorax. He thinks that for the duration of the pneumothorax therapy, perhaps for several years, the children should remain

in an institution unless the home conditions are especially favorable and permit regular refilling of the pneumothorax and careful supervision. Schooling and manual training of the children during this time of institutionalization can be handled most successfully in connection with a work sanatorium for adults.

- Aleukemic Lymphadenosis with Hyperchromic Megalocytic Anemia. W. Christen and S. Greif.—p. 85.

Protamine Zinc Insulin and Diabetes Refractory to Ordinary Insulin.—Taubenhaus says that not much attention had been paid to the effect of protamine zinc insulin in insulin resistant cases of diabetes. The author raised the question whether such cases could be treated with protamine zinc insulin in which, as the result of simultaneously existing complications (hypertension, coronary sclerosis, hemorrhagic retinitis and so on), ordinary insulin, according to the opinion of some investigators, should be given not at all or only in small doses. These cases generally show a persistently high blood sugar content but only a slight glycosuria, and small amounts of ordinary insulin often are without effect. The author reports four cases of this type. Treatment with ordinary insulin had been without effect, but protamine zinc insulin produced surprisingly favorable results. The author is unable to give a satisfactory explanation of this phenomenon but suggests that protamine zinc insulin, as the result of its slow action, elicits only a weak counter regulation and thus forces a reduction in the blood sugar. The action of protamine zinc insulin resembles the endogenic action of insulin more than does that of ordinary insulin. An increase in the sensitivity to insulin seems to have taken place, which may have been effected by the zinc. Further observations convinced the author that the favorable effect of protamine zinc insulin is not the rule, however. He cites a case in which it failed. Nevertheless, its efficacy in some insulin resistant cases proves that this resistance is only relative.

Intermittent Claudication.—Kisch applies the symptomatologic term of intermittent claudication to disease processes which consist in chronic obliterating processes in the arteries of the leg, without paying attention to the clinical differentiation between arteriosclerosis obliterans and thrombo-angiitis obliterans. On the basis of fifty-three cases of intermittent claudication, he demonstrates the value of his simple work test in estimating the blood perfusion of the impaired vascular region. In this test intermittent claudication is induced by a standard exertion, an exercise which is repeated at the rate of thirty times a minute and consists of a maximal bending and a maximal extension at the ankle, knee and hip joints while the patient is in the horizontal position. The number of times the standard exertion has to be repeated indicates the status of the compensatory circulation on the part of the collateral vessels in the impaired muscular region. An increase in the number of exertions necessary to elicit an attack is an indication of improvement; a reduction, however, is a sign of exacerbation. The author cites three cases of intermittent claudication in which he resorted to the sublingual administration of 3 drops of 1 per cent alcoholic solution of glyceryl trinitrate. The work test revealed that the treatment produced an improvement in two of the cases, but not in the third. Other vasodilating drugs employed by the author were theophylline with ethylenediamine, caffeine and alcohol, the latter in the form of brandy or whisky. Influences likely to cause further impairment, such as pressure, cold, heat and misuse of tobacco, were avoided as much as possible. Moreover, care was taken that adequate amounts of water were taken and that elimination was regular. The combination of these measures together with the aforementioned vasodilating medicaments produced a considerable improvement in 45.2 per cent and a moderate one in 30.2 per cent of the cases. In the remaining cases, however, there was no betterment.

Changes in Chronaxia of Vestibule of Internal Ear.

Wasowski and Hurynowiczówna report their experiments on twenty-seven rabbits accustomed to chronaximetric research of the vestibule of the ear. They made 186 observations with Bárány's method. They arrived at the following conclusions: Irritation of the labyrinth of the ear with cold and warm water causes a clearcut increase in the excitability of the vestibules, expressed by a decrease in the chronaxia. The increase in excitability after the action of cold water is most clearly marked on nystagmus (32.8 per cent of decrease in chronaxia), a little less on the deviation of the head (31 per cent) and still less on the deviation of the eye (20.46 per cent). Irrigation with hot water caused a great increase in deviation of the eye (chronaxia decreasing to 49.48 per cent), lessened the deviation of the head (decrease in chronaxia by 29.99 per cent) and showed least in nystagmus (decrease to 12.42 per cent). The character of the modification of the excitability in the vestibules after the action of cold water is similar to the changes artificially caused in anemia.

Irradiation with Roentgen and Radium Rays in Infectious Processes. D. Den Hoed.—p. 1093.

Experiences with Calcium-Bromide Preparation in Treatment of Epilepsy. A. Q. Van Braam Houckgeest.—p. 1096.

Cutaneous Manifestations of Scurvy.—Renders reviews the literature on the cutaneous manifestations in scurvy. Among others he mentions Strümpell's observation of the dry and exfoliative character of the skin during the latent stage of scurvy, the so-called keratosis suprafollicularis described by Aschoff and Koch, the papulokeratotic scorbutic dermatitis of Nicolau, the scorbutic pemphigus of Litton, the scleroderma-like disorder of scorbutic patients described by Morawitz and Pfeiffer and so on. Discussing the "keratosis suprafollicularis," he points out that Morawitz regards this disorder as the result of a nonspecific nutritional disturbance and that Gottron likewise is of the opinion that the disorder has no connection with scurvy. After mentioning the changes on the mucous membranes the author describes the clinical histories of six patients with scurvy. He gained the impression that keratosis suprafollicularis has no value for the diagnosis of incipient scurvy. In one of the patients he observed a scleroderma-like change on the legs, as had been observed by Morawitz and Pfeiffer in patients with scurvy.

Vitamin B₁ Metabolism and Pregnancy.—Westenbrink and Goudsmit discuss their observations on the vitamin B₁ metabolism in pregnant women. They found that nonpregnant women from the poor population of Amsterdam excreted less vitamin B₁ in their urine than did nonpregnant women who received a rather generous diet. It was observed that pregnancy exerted a noticeable influence on the excretion of vitamin B₁. With as well as without additional administration of vitamin B₁, pregnant women excreted on the average considerably less vitamin B₁ than did the nonpregnant women who might be supposed to be living on about the same diet. With only a few exceptions, the pregnant women were far from saturated with vitamin B₁. Since deficiency in vitamin B₁ may be accompanied by changes in the tongue, gastrointestinal disturbances, paresthesias, fatigue, edemas, changes in the blood and so on, such symptoms were sought among the twenty pregnant women from among the poor classes of Amsterdam. There was one group

entirely free from these symptoms or with only one slight complaint and another group which had several of these symptoms. In the first group the vitamin B₁ excretion was greater than in the second group; the food intake likewise was more adequate in the first than in the second group. These investigations demonstrate the usefulness of the authors' thiochrome method for the detection of vitamin B₁ deficiencies.

63: 139-320 (No. 3) 1938

*Diagnosis of Intestinal Tuberculosis as Complication of Pulmonary Tuberculosis: Roentgenologic and Clinical Study. F. Tisell.—p. 139.

Intestinal Tuberculosis.—Tisell reports 178 cases of pulmonary tuberculosis with and without intestinal tuberculosis in which in most instances there was cavitation with bacilli in the sputum. Intestinal tuberculosis was demonstrated after death in fifty-four of sixty-one cases (88.5 per cent); in all but one there were changes in the ileocecal region. Anatomopathologic examination of the intestine after formol fixation showed prominent formation of folds in the mucous membrane. This formation is believed to act as a preventive mechanism. In cases in which there was extensive defect of the mucous membrane and greatly affected muscularis there were no folds; the wall was rigid and often infiltrated with connective tissue and the lumen often narrowed. In these cases the roentgenogram showed the ulcerations as small, closely situated undulant contour defects. Otherwise the x-ray appearance was dominated by the formation of folds in the mucous membrane, the ulcerations being to a large extent hidden by the folds. When the formation of folds was marked, the lumen was almost closed (Stierlin's symptom). Single small superficial ulcerations in the cecum could not be demonstrated roentgenologically. The author says that roentgen examination affords the best aid in the demonstration of ileocecal tuberculosis; roentgen demonstration of changes in the small intestine is less reliable. Localization of roentgenologic changes in the ileocecal region and simultaneous pulmonary tuberculosis support the diagnosis of intestinal ulcerations. Rigidity of the wall and the presence of the contour defects constitute the best evidence. Intestinal tuberculosis was diagnosed as roentgenologically probable in forty-eight of fifty-four cases in which necropsy revealed ulcerations in the intestine. In no case in which the intestine was normal after death had intestinal tuberculosis been the probable roentgen diagnosis. Symptoms of stenosis were observed in twenty-four of forty-seven cases in which there were ulcerations in the small intestine (51 per cent). The roentgenogram was positive in forty of forty-eight cases in which there was ulceration in the cecum (83.3 per cent). Single ulcerations in the terminal ileum could also give positive roentgen results. Diagnosis based only on the clinical picture was often unreliable. In 40 per cent of the cases in which there were roentgenologic changes, colicky pain and diarrhea were lacking. When either of these symptoms is absent, certain clinical diagnosis is impossible; roentgen examination allows probable diagnosis before their appearance. Constipation is a fairly early sign in intestinal tuberculosis. Marked tenderness to pressure in the abdomen and palpable tenderness in the right iliac fossa make the diagnosis probable, especially if accompanied by pain and loose stools. As deductions from the temperature can be made only when active pulmonary tuberculosis is excluded, this factor is of limited diagnostic importance. The increased sedimentation in intestinal tuberculosis is also of restricted value, as in these cases the pulmonary tuberculosis is usually progressive. Tubercle bacilli in the feces afford no proof of intestinal disturbance. Tisell is inclined to connect the origin of intestinal tuberculosis with diminished local or general immunity to infection. In most cases of demonstrable intestinal tuberculosis the pulmonary tuberculosis was extensive. In one third of all roentgenologically positive cases the interval between the onset of the pulmonary tuberculosis and of the intestinal tuberculosis was less than half a year. After an observation period of two and a half years, 80 per cent of all patients with roentgenologically positive intestinal tuberculosis were dead; the outcome is ascribed to the grave nature of the pulmonary disorder.

PREMENSTRUAL TENSION

S. LEON ISRAEL, M.D.

PHILADELPHIA

Premenstrual tension is the term applied by Frank¹ to a relatively uncommon train of symptoms which occurs cyclically during the premenstruum in certain women of child-bearing age. As current literature is devoid of reports on this subject, its actual incidence cannot be estimated. The fact, however, that my associates and I have encountered the condition in fourteen women during the past three years suggests that it may be more frequent than is now suspected. The opportunity to study and treat ten of the group has led to a plan of management of premenstrual tension which seems to yield excellent therapeutic results and deserves a wider application. In pursuance of the latter thought, this report has been written.

SYMPTOMS

The unpleasant symptoms which 40 per cent of normal women suffer, in varying degrees, before the onset of menstruation are well known. Minor menstrual molimina may be manifest as fatigue, irritability, lack of concentration, backache and a vague sensation of pelvic discomfort. When the latter assumes the major proportions of a disabling pain, it is properly termed dysmenorrhea. I am not concerned herein with the problem of dysmenorrhea but rather with the pathologic manifestations of some of the normal menstrual complaints, manifestations sufficiently intense and delineated to deserve recognition as a morbid entity. Dysmenorrhea may or may not accompany the syndrome.

When well marked, premenstrual tension is readily recognized. It occurs in women between the ages of 20 and 40 years and is characterized by a cyclic alteration of personality. This alteration appears abruptly from ten to fourteen days prior to the expected menstruation and terminates dramatically with the onset of the flow. The monotonous periodicity of the syndrome and its precursive relationship to the menses are striking phenomena. The illness regularly begins as a dire and foreboding sensation of indescribable tension. The patient often inadequately describes this sensation by saying that she "would like to jump out of her skin," and her feeling is manifest to observers by her unusual behavior. When the tension periodically reaches its maximum height, the manic activity of the patient beggars description. There are marked

physical unrest and constant irritability. The illness may mimic an oncoming mental disease when the more exhausting episodes of motor activity are followed by brief periods of depression and hebetude. The forbearance of the patient's family is taxed beyond endurance by her unnatural and extreme annoyance with trifles. Unreasonable emotional outbursts and causeless crying spells, similar to those which characterize the menopausal syndrome, are frequent. Persistent insomnia, vertigo, painful turgidity of the breasts and constant headache are frequent accompaniments of the syndrome. Nymphomania, when present, is an arresting symptom and commands the deepest sympathy.

The curious phenomenon of premenstrual ulcerative stomatitis, attributed to defective luteinization,² may be one of the manifestations of premenstrual tension. It was the major complaint of one of the patients in the present series.

As with any clinical entity, not all the symptoms may be present in a single patient. The following case history, that of a patient selected from a group of fourteen similar patients (table 1), exemplifies the periodic frenzy of premenstrual tension and suggests an effective treatment.

REPORT OF CASE

M. T. C., a white woman, aged 34, the twice-divorced sister of a physician, was first seen May 7, 1935, with severe premenstrual symptoms. Her past medical history included an appendectomy, two induced abortions, one full term pregnancy and a vaginal plastic operation. Her menstrual history was normal, with thirty day cycles since the age of 13.

Her present illness was of seven years' duration and entirely cyclic in character, existing only during the premenstruum and increasing in intensity with the passage of years. During the major portion of the month the patient was a quiet, industrious, mild mannered woman, but exactly ten days prior to each menstruation she changed to an irritable, tensely restless, irascibly shrewish creature with headache, insomnia and nymphomania. The last symptom was outstanding because the greatly increased libido could not be stifled and the patient, despite frequent coitus, was forced to masturbate from fifteen to twenty times daily. This alteration of personality terminated abruptly at the onset of menstruation, only to reappear in twenty days. It was difficult for one who had observed the patient during several cycles to reconcile her dual personality.

General physical examination revealed no abnormalities, and the pelvic organs were in exceptionally good condition. Her height, weight and blood pressure and the results of serologic tests, urinalysis and a complete blood count were within normal limits. Single determinations of the estrogen content of both the blood and the urine during the height of the tension showed no deviation from the normal.

During the past seven years the patient's treatment had included physical therapy, sedatives, psychotherapy and estrogens. The last named, administered hypodermically in two

courses, had definitely aggravated the symptoms. Bearing this fact in mind and ascribing the syndrome to defective luteinization, I gave the patient intramuscularly 1 international unit of corpus luteum principle, progesterone, daily from the eighteenth to the thirtieth day of the menstrual cycle for three successive months. During this period the patient remained entirely symptom free. However, a relapse occurred during the succeeding month, when no treatment was given. Immediately thereafter, with the hope of permanently rectifying the probable gonadal dysfunction, low doses of radiation to the pituitary gland and the ovaries were administered in three weekly exposures of 50 roentgens each. Since this treatment of two years ago, the patient has been free from the premenstrual tension and has continued to menstruate regularly.

ETIOLOGY

Fifty years ago Jacobi³ expounded the "menstrual wave" theory and ascribed the menstrual molimina to a cyclic ebb and flow of somatic functions. However,

Endometrial specimen obtained on the first day of menstruation from a regularly menstruating woman, aged 34, with premenstrual tension. Note the total absence of secretory (progesterone) changes. Slightly reduced from a photomicrograph with a magnification of 100 diameters.

not until 1931, when Frank¹ reported fifteen cases of premenstrual tension, did a seemingly plausible explanation of the cause exist. Frank determined the levels of estrogen in the blood and the urine of his patients and, finding a high renal threshold for the substance, hypothesized a hormonal pathogenesis for premenstrual tension in certain "labile" women. Such women, according to Frank, do not excrete estrogen in a normal manner. During the premenstruum, the concentration of estrogen in the blood rises and affects the sympathetic nervous system to the extent of the symptoms produced.

In the present series, only four of seven women whose blood and urine were assayed premenstrually

for estrogen exhibited a high renal threshold. The fact that the renal threshold for estrogen is not uniformly elevated bespeaks another explanation for the syndrome. It is suggested that premenstrual tension is caused, not by an excess of circulating estrogen, but rather by the presence of unantagonized estrogen. This implies that the primary cause of premenstrual tension is deficient ovarian luteinization, with a decreased production of progesterone. The fact that the symptoms arise during the period of corpus luteum activity further strengthens this supposition. Additional evidence may be adduced from the endometrial studies of four women in the present series. Three of the four patients, curetted just prior to or on the first day of a menstrual flow, showed the phenomenon of pseudomenstruation, cyclic uterine bleeding from an endometrium lacking the secretory influence of the corpus luteum hormone, progesterone. Two of these three women were found to be bleeding from an interval (proliferative) and one from a hyperplastic (exaggeratingly proliferative) endometrium. As pseudomenstruation is caused by failure of ovulation with subsequent absence of luteinization or by quantitative disproportion in the production of the ovarian hormones, estrogen and progesterone,⁴ its frequent occurrence in women with premenstrual tension supports the hypothesis of an aberration in the luteinizing process. In the light of our present knowledge, such an abnormality may be caused by deficient production of the anterior hypophysial luteinizing factor or by a refractory state of the ovaries. In either case the immediate result would be a lack of the corpus luteum hormone, progesterone. It may be possible in the near future to detect such a deficiency by employing the recently introduced technic of Venning⁵ for the assay of urinary pregnandiol, a degradation product of progesterone.

On the other hand, if the pathogenesis of premenstrual tension is as herein advanced, namely, a cyclic disturbance of normal luteinization, with deficient production of progesterone, why is it not more frequently encountered in women with pseudomenstruation? This and other questions besiege the validity of the hypothesis. Although it may not yet be proved, the theory does provide a rational mode of therapy for premenstrual tension.

TREATMENT

The treatment of premenstrual tension does not, in the absence of a proved etiology, rest on a solid foundation. Frank¹ employed nonspecific eliminative measures or roentgen castration, depending on the severity of the symptoms. Theoretically, assuming defective luteinization to be the cause of the disorder, the administration of the pituitary-like gonadotropin (luteinizing factor) should correct the condition promptly. Practically, however, the currently available doses of luteinizing substances, obtained either from extracts of the anterior hypophysis or from pregnancy urine, do not uniformly effect luteinization in human ovaries. Gonadotropic hormone therapy may become clinically effective when large doses, such as 25,000 rat units,⁶ are employed.

In view of the probable cause of premenstrual tension, namely, defective luteinization, with progesterone

The despite the lack of an adequate from premenstrual tension for the courses of progesterone.

Permanent results, we subsequently irradiation of the pituitary gland of the progesterone-treated patients patients who had received no previous roentgen treatments were administered who followed the technic outlined includes three treatments of from is at weekly intervals to both the pituitary fields. In a patient of average factors for each treatment are 127 amperes, 14 inch distance, 5 mm. for three to five minutes (Edeiken). Patients so treated have remained free of tension during observation periods and a half to two and a half years. Two patients were also symptom free

after the roentgen therapy, but they suffered recurrences of the syndrome after six months and two years, respectively. Both patients received second courses of low dose irradiation and have now been well for more than a year. The periodicity of the menstrual cycle was undisturbed in all the women treated by roentgen rays.

The mechanism by which low dose irradiation corrects functional alterations of the pituitary gland and ovaries is a moot question, and the rationale for its use is purely empirical. However, the safety and value of radiation when properly administered have been adequately demonstrated in the reports of Rubin,¹⁰

Drips,¹¹ Mazer and Spitz,¹² Kaplan¹³ and others. Despite the fact that its greatest field of usefulness is in the treatment of certain types of menstrual irregularities, low dose irradiation of the pituitary gland and the ovaries may be applicable in the treatment of regularly menstruating women with functional aberrations of the gonads. It is of course an obvious corollary that the radiation must be administered in controlled doses by a competent radiologist.

One of the ten women who submitted to treatment (table 2) was markedly underweight and for eight

weeks was given 8 units of insulin twice daily plus a diet rich in carbohydrate. She gained 17 (7.7 Kg.) pounds, and the premenstrual tension disappeared (follow-up, two years). This observation is interesting in view of the effectiveness of insulin therapy in selected instances of pseudomenstruation.⁴

SUMMARY

The syndrome of premenstrual tension in fourteen women was ascribed to defective luteinization, with subsequent progestin deficiency or relative hyperestro-genemia.

As the harassing symptoms arise during the height of supposed corpus luteum activity and are aggravated by estrogen therapy, substitutive treatment with progestin seemed plausible. Low dose irradiation of the pituitary gland and ovaries was employed in the hope of permanently correcting the probable gonadal defect.

The administration of progesterone (crystalline corpus luteum principle) cured one and temporarily relieved six patients with premenstrual tension. Four of the six and two additional patients were subsequently cured by low dose irradiation to the pituitary gland and the ovaries. One malnourished patient was benefited by a gain of weight, aided by insulin therapy.

The Father of American Psychiatry.—In that year Dr. Benjamin Rush joined the staff of physicians at Pennsylvania Hospital, beginning a thirty year period of service that was fraught with great significance to the mentally ill in America. He was the first American teacher to institute a comprehensive course of study in mental disease; he was the first American physician to attempt an original systematization of the subject. The theoretic structure that he erected was decidedly unsteady, as we shall see, but it marked a real beginning, and an honest one. He wrote the first general treatise on psychiatry in America, and it is no mean tribute to his genius that it remained the only American work of its kind for seventy years after publication. He fully earned the title by which he was known to later generations—"the Father of American Psychiatry."—Deutsch, Albert: *The Mentally Ill in America*, New York, Doubleday, Doran & Co., Inc., 1937, p. 72.

PRESSURE ON THE BRACHIAL PLEXUS CAUSING SIMULATION OF CORONARY DISEASE

WILLIAM D. REID, M.D.

BOSTON

A series of patients has been observed in which the pressure of a cervical rib or the scalenus anticus muscle on the brachial plexus has been the cause of pain simulating angina pectoris. It is obvious that these diagnoses differ significantly in prognostic and therapeutic implications. The delay experienced by some of these patients before the correct diagnosis was achieved gives me ground for the belief that some discussion of the subject may prove timely.

Pain due to pressure on the brachial plexus is given but scant attention in nonsurgical literature. The occurrence of precordial pain and the simulation of angina pectoris or coronary thrombosis is rarely mentioned.

GENERAL DESCRIPTION

Fischel of Prague is said to have found cervical ribs in 1 per cent of all autopsies.¹ Adson and Coffey² state that 55 per cent of the persons in whom they found cervical ribs to be present had no symptoms. It is estimated that perhaps 10 per cent of persons with this condition have symptoms.

The cervical rib may be attached to any cervical vertebra from the second to the seventh. The costal syndrome may be present when the costal element of the seventh cervical vertebra is merely exaggerated.³ Sometimes the abnormal structure is a fibrous cord which acts like a cervical rib but cannot be visualized on the roentgenogram.¹ In fact, cases are met in which the syndrome is present in the absence of a cervical rib;⁴ an abnormality in the relation of the first rib and the brachial plexus is the cause.

The syndrome has been explained⁵ as due to a friction neuritis; the nerves are made taut across the sharp edge of the rib as the result of various unfavorable conditions in the relations of the nerves to the bony structures. More recently attention⁶ has been directed to the effect of the scalenus anticus muscle causing pressure on the subclavian artery or brachial plexus, or both. This muscle (fig. 1) extends between the transverse processes of the third to the sixth cervical vertebra downward to the scalene tubercle of the first rib. The scalenus anticus may compress the artery or nerves against the cervical rib, if such is present, or it may abnormally elevate the first rib and so interfere with the artery and plexus. If the latter is irritated the scalenus anticus muscle, which receives its innervation from the brachial plexus, may be stimulated to a state of spasm. A "vicious cycle" may be said to exist. The important part played by the scalenus anticus muscle and the fact that it may cause symptoms identical with

pressure by a cervical rib, in cases in which there is no extra rib, is the justification for the term "scalene anticus syndrome."

The average age at which symptoms first appear is 30 years. This delay is explained⁷ as due to the high position of the shoulder girdle in youth, symptoms being less prone to develop when the shoulder girdle is higher. During childhood and adolescence there is progressive descent of the shoulder girdle, which does not attain its final position until adult life. In some persons a further droop may be acquired as a result of faulty posture.

Pain, paresthesia and anesthesia in the area supplied by the affected nerve are the usual symptoms. The pain is neuralgic in character: it may begin in the neck, spread downward along the arm to the hand and sometimes the reverse way to the head and side of the chest. Rotation of the head toward the affected side or a downward pull on the shoulder may increase the pain. Loss of or decrease in amplitude of the radial pulse and a bruit over the clavicle are other symptoms and signs that may be noted.

Fig. 1.—Compression of lower and middle cords of brachial plexus and of subclavian artery, between cervical rib and scalenus anticus muscle: a, scalenus anticus; b, cervical rib; c, upper and middle trunks of brachial plexus; d, lower cord of brachial plexus and subclavian artery; and e, first rib (Bickham's Operative Surgery).

A dilatation or actual aneurysm⁸ of the subclavian artery may be caused just beyond the point of constriction. Halstead⁶ found this condition in twenty-seven of 716 cases presenting cervical rib.

The simplest form of treatment⁷ is that of elevation of the shoulder upward and backward by a sling. Physical therapy is then used in an attempt to develop the trapezius and levator anguli scapulae muscles. If such measures prove unsuccessful and the symptoms warrant it, surgical treatment is advised. Operations are described⁸ for removal of the cervical rib or first rib, whichever is the cause of the pressure on the brachial plexus or subclavian arteries. A considerable number of patients have been relieved by section of the scalenus anticus muscle without removal of the bone (fig. 2).

REPORT OF CASES

CASE 1.—A housewife, aged 59, complained of pain in the left arm and over the precordia. An electrocardiogram was taken because of an irregularity in the cardiac rhythm. This was found to be due to sino-auricular block, and because such rhythm unusual in an adult it was suggested that a search be made for something, such as a tumor or a cervical rib, causing pressure on the nerves in the neck.

This suggestion was followed out by Dr. Henry J. Bakst, to whom I am indebted for the notes on this case. The original notes were inadequate because of language difficulty.

The patient had felt fairly well until about one month before, when she noted the onset of a severe burning pain in the left side of the chest anteriorly, the left axilla, the shoulder and the inner surface of the left upper arm. This pain was markedly increased when the patient lay on the left side. She also noted that a feeling of weakness and faintness followed when she was lying on the left side; there was no actual syncope. During the past month weakness of the left arm was experienced when she attempted to lift objects. Numbness and tingling of the fingers of the left hand had been noted during the past month. One week before admission slight swelling of the entire left arm with numbness appeared and persisted for two days. Dyspnea after ascending one flight of stairs had been present for several months; the pain in the chest and arm was accompanied by moderate dyspnea. Some vertigo had occurred during the past month.

The neck was not remarkable except for a hard, rounded swelling apparently extending from the cervical spine and palpated in both supraclavicular areas. Pressure on this mass in the left side of the neck caused pain locally and over the lower precordia and left upper arm.

The heart was normal except for occasional intermissions or gaps in the cardiac sounds.

There was some muscular weakness of the left arm but no abnormality of reflexes. The blood pressure was 164 systolic, 96 diastolic.

X-ray examination showed that the heart was normal in size and contour. There was moderate sclerosis of the thoracic aorta. Cervical ribs on the right and left were revealed. There was fibrosis of the right upper lobe of the lungs.

The remainder of the history and examination were irrelevant or normal.

The patient was seen by a surgeon and operation was advised but the patient declined surgical therapy.

CASE 2.—A man, aged 61, a "red cap" at a railroad station, complained of pain in the right shoulder and arm. He has noted a little shortness of breath during the last three weeks when carrying bags for customers. The pain in the right shoulder and arm is experienced at the same time. This pain is located on the top of the shoulder and down the inner aspect of the right arm to the elbow. The arm at these times feels a little weak. The patient tries to shield himself by going slowly and avoiding excessive weight on the right arm.

Physical examination was normal except for a hard mass in both supraclavicular fossae. These masses feel like bones and can be traced back to the lower cervical spine. The subclavian artery, especially on the right, is readily palpable and perhaps a little sclerosed.

Roentgen examination disclosed bilateral cervical ribs and the heart to be normal in size, contour and contractibility.

CASE 3.—A housewife, aged 39, has rheumatic heart disease, mitral stenosis and insufficiency, and aortic insufficiency. She was first informed of her cardiac impairment at the birth of her first child six years ago. She is being guided by the outpatient clinic and has relatively little in the way of symptoms or signs of cardiac insufficiency.

It was noted at a recent visit that she complained of a pain which she says "started in the right neck, went to the right axilla and settled under the right breast." This pain was made worse by lifting with the right arm; the pain might persist for an hour or more. She has noted this particular pain at times during the past six years.

Examination failed to detect a palpable cervical rib. Faulty posture and a low lying shoulder girdle were marked. The x-ray examination disclosed no cervical rib, but a very horizontal clavicle, low lying shoulder and prominent first rib.

The fact that three of these patients were observed within a period of three months offers reasonable ground for the belief that the syndrome is not rare. Doubtless recognition of the first case caused us to detect others more readily. Palpation of cervical ribs is not always easy, and in the case of a number of patients sent for roentgen examination it was found that what was palpated was merely a prominent transverse process of the seventh cervical vertebra. None

Fig. 2.—On the left, conditions causing compression; on the right, relief by surgical operation: I, Cervical rib and fibrous band to first thoracic rib; II, fully formed cervical rib; III, fully formed cervical rib; V, same as III except that compression of subclavian artery in addition to the lower cord of the brachial plexus is shown. For identification of structures see figure 1 (Bickham's Operative Surgery).

of the latter patients had symptoms warranting treatment for pressure on the cervical plexus.

Regarding the cases cited: The diagnosis of the first patient was obvious after one thought to palpate the neck for a bony mass which could account for the symptoms by pressure. Surgical treatment seemed clearly indicated but has not yet been accepted by the patient.

The second patient should cause little diagnostic confusion, although it is admitted that he was referred to the cardiac clinic, provided one considers that not all pains in the shoulder and arm are due to angina pectoris. It was found on further questioning that this man had been employed as a washroom attendant for years and noted the pain in the shoulder and arm

only after transfer to his present work, which involves a downward pull on his right arm. A change of occupation may well be the best treatment for this patient.

The third patient caused some doubt regarding the correct diagnosis, because of the absence of a cervical rib in the roentgenogram. However, consultation of a textbook³ made it apparent that orthopedists recognize the pressure syndrome in the absence of a cervical rib but with abnormal relations between the shoulder girdle and the first rib. What the writer palpated was probably the unduly prominent first rib. Fuller appreciation of the significance of the poor posture of this patient came after reading the description by Jones and Lovett.³

CASE 4.—A housewife, aged 36, complained of precordial pain and dyspnea. There was slight dyspnea on exertion. She would have slight precordial pain "when nervous." There was moderate palpitation. The patient would get spells of nervousness during which she had vertigo and difficulty in speaking. At these times she would feel weak all over.

She had been treated for heart disease because of shortness of breath for the past five months. During the past month she has had a dull precordial pain, which comes on usually when she is tired. There is sometimes pain in the left arm at the same time as the precordial ache. The pain is never sharp or severe and has a duration of about half an hour. The roentgenogram of the chest disclosed a cervical rib on the left side.

There was a bony prominence with a marked systolic pulsation over it in the left supraclavicular fossa. A rough systolic murmur could be heard over the bony mass. Pressure on the mass on the left side of the neck caused slight numbness in the left hand. There was slight dulling of sensation on the left side of the neck. The right supraclavicular fossa contained a similar but less prominent mass and without the murmur or symptoms on pressure.

The heart was normal except for a faint murmur over the apex impulse.

Roentgen examination showed the left cervical rib articulating with the first thoracic rib. The cervical and thoracic sections of the spine were normal.

The rib was removed by operation. The pain gradually disappeared during the subsequent two weeks. The patient noted that after the operation she was able to swallow better; prior to operation she had overlooked a moderate degree of dysphagia.

The fourth patient is selected from the hospital records; I am uncertain whether I myself examined her. Save that the precordial pain was, as the word implies, left sided, the pain syndrome was similar to the last of the cases cited. These last two patients appear to support each other; the former had definite heart disease plus the scalenus anticus syndrome, and the latter the scalenus anticus syndrome without heart disease. Her former physician found it difficult to accept the cure of his patient by excision of the cervical rib, but a cure has resulted. It should be noted that the pain subsided in the course of two weeks rather than immediately after operation; some degree of neuritis may well have been present.

An additional interesting case has been brought recently to my attention by Dr. Henry J. Bakst. The patient is a man, aged 29, who complained of precordial pain. The onset of the pain occurred six years ago; it has radiated to the left arm during the past year and is increasing in frequency and duration. The pain appears in association with exertion and is particularly severe after an attempt is made to walk with the shoulders back—the patient's usual posture is slightly stooped or round shouldered. Physical examination was normal save for left scoliosis of the spine, which straightens on bending, round shoulders, the left

shoulder higher than the right, and pronation of the feet. The patient was referred for orthopedic treatment—arches and exercises—and after two weeks of this has been completely relieved.

A noteworthy feature of these cases is that four of the five patients experienced pain in the anterior aspect of the chest or precordium, a fact that, as far as I am aware, has received little if any attention in the literature. The presence of precordial pain naturally caused an increased tendency to confuse this scalenus anticus syndrome with cardiac disease.

Since the foregoing was written an article⁴ has appeared which emphasizes the frequent association of a painful shoulder, due to neuritis of the brachial plexus with angina pectoris or coronary thrombosis. The shoulder condition may precede the cardiac disease or vice versa, and either appears to aggravate the other. The patient with brachial neuritis following a coronary infarction need not be kept in bed indefinitely; he may be ambulatory and his recovery accelerated by physical therapeutic measures, such as diathermy.

Although the pain complained of by these patients was in the same location and induced by exertion, angina pectoris was not really present. Only certain forms of exertion, such as a downward pull on the shoulder and turning of the head to one side, appear to provoke pain; other forms of exertion are not pain inducing. Often the pain does not cease promptly on cessation of the exertion; in fact, it may persist when the patient is at rest in bed and require differentiation from that associated with coronary infarction. The absence of the remainder of the picture of coronary thrombosis (shock symptoms, changes in the heart sounds, fever, leukocytosis, acceleration of the sedimentation rate, electrocardiographic changes and the like) and the undue persistence of the pain, in case a true brachial neuritis is present, should serve to exclude the cardiac diagnosis.

It is true, nevertheless, that the difference in the pain, as in the cases cited, may not be obvious unless the patient is questioned carefully and the lateral aspects of the neck are examined. Doubtless awareness of the fact that conditions in the neck may cause symptoms simulating either angina pectoris or coronary thrombosis is the most important factor in preventing an error in diagnosis. It is repeated that either brachial neuritis or coronary disease, or both, may be present in the same individual.

CONCLUSIONS

Pressure on the brachial plexus (by cervical ribs, the scalenus anticus muscle and tumors) may cause pain simulating either angina pectoris or coronary thrombosis.

Precordial pain may be so induced, and some relation to exertion may be manifest.

The presence of a cervical rib is not essential.

Pain caused by pressure on the cervical plexus is probably relatively common.

Consideration of both diagnoses—cardiac and that of the brachial plexus—should prevent a mistake in diagnosis.

Differentiation of two conditions may be of great importance to the patient.

HEAD TRAUMA

REPORT OF 141 CASES

NICHOLAS GOTTEN, M.D.

MEMPHIS, TENN.

The incidence of automobile accidents has increased to such an extent that public attention is being directed to the problem. The attendant bodily injuries make the treatment one of the few surgical problems of public welfare. Because of these injuries, increased attention on the part of both hospitals and physicians must be directed to their care. A large percentage of these cases present head injuries which are attended with a high mortality. My purpose in this paper is to analyze carefully a series of 141 consecutive cases of head trauma admitted to the Neurological Service at the Jewish Hospital, Philadelphia, from May 1933 to May 1936.

Among the many reports in the literature on the treatment of head injury, too few contain careful uniform statistics, and frequently there is no uniform method of analysis. This results in a great variation in accepted modes of treatment. For example, some hospital statistics show death rates as high as from 35 to 50 per cent in cases of "head injury," while others report rates as low as 10 per cent. Wortis and Kennedy¹ reported 1,000 cases of head trauma from the Bellevue Hospital with a mortality of 37.8 per cent. Swift² reported a large series of cases with a mortality of 25 per cent, while Fay's³ most recent report has only a 13.8 per cent death rate in 556 cases. That these results are obtained by surgeons particularly interested in the treatment of head injuries shows that there must be reasons why the figures vary so much. On careful analysis, the variation in statistics is found to be due to three factors; the method of analysis of cases, the hospital routine for receiving this type of patient and the method of treatment.

The series of 141 consecutive cases of head trauma here reported has been handled with these three premises in mind. The cases were classified with a rigid definition of head trauma; i. e., a period of unconsciousness of at least five minutes, a subarachnoid hemorrhage or a fractured skull. The hospital routine and organization were perfected. The nurses and interns were given lectures and instructions in the methods employed, and treatment in the wards was at all times made under personal supervision.

MORTALITY

There were fifteen deaths in this series, giving a mortality rate of 10.6 per cent. It is of particular interest to separate these cases into age groups. There were sixty patients under 20 years of age, sixty-six between 20 and 60 and fifteen over 60. The mortality rate was 5 per cent in the group under 20 years of age, 10.6 per cent in the second group, and 33.3 per cent in the group over 60 years of age. These results are in agreement with the observations of Swift,² who obtained the lowest mortality in children and adolescents.

Reviewing the data from the standpoint of the decade of life in which the injury occurred, the following deductions may be made: If a patient is under 20 years

of age he has approximately a twenty to one chance of recovery from head injury. If between the ages of 20 and 60, his chances of recovery are reduced to ten to one, whereas if he is over 60 his chances are only three to one. The figures just computed are not related to the severity of the injury. For instance, a number of children recovered who had severe crushing injuries with loss of cerebral tissue, while an apparently very mild cerebral injury in the elderly group was often a sufficient precipitating factor to cause death. Seven of the fifteen patients who died were over 60. Complications secondary to the injury were the chief factors causing death in the aged. For example, in one patient, 69 years of age, an acute cardiac decompensation developed, another, 66 years of age, went into delirium tremens, while in a third, 60 years of age, uremia developed after rather mild trauma.

Among the fifteen deaths, particular attention is directed to a group of four cases because of the similar but unusual clinical courses. Their respective ages varied, being 66, 35, 34 and 19 years. In these cases the trauma was apparently not severe. On admission the patients were more restless and irrational than unconscious. The pulse, blood pressure and respiratory rate were within normal limits. The physical and neurologic examinations were negative except for the irrational state. The spinal fluid was only slightly bloody, if at all, and the pressure of the fluid was consistently low. On first examination the injuries did not appear to be very severe and one expected the patient to regain full consciousness within a few hours. However, the stupor gradually deepened and the patients died within three to ten days. The blood pressure and pulse remained normal and well maintained until the terminal stage. None of the usual remedies were of benefit.

The cause of death in these cases is obscure. No postmortem examinations were possible. It is likely that death was due to widespread multiple areas of softening of the brain associated with petechiae and initial swelling of the smaller blood vessels, as described by Winkelman and Eckel.⁴ They showed that, in acute trauma, multiple areas of softening occurred and that the histologic picture was not different from that seen in the brains of patients suffering from severe infections and intoxications. It may be that the sudden lowering of blood pressure during shock starts a vicious cycle of cerebral edema that cannot be overcome.

OPERATIONS

Of the 141 patients, seven underwent operations. Of these, four recovered and three died. Three children with depressed fractures recovered completely following decompression and removal of bone fragments. One patient⁵ with a traumatic aneurysm of the internal carotid artery recovered after ligation of the common carotid artery. The three remaining patients were diagnosed as suffering from mass hemorrhage. In two of these a blood clot was found and removed, while in the other severe brain contusion was demonstrated at operation. All three patients died. The operative mortality was 42.8 per cent, the non-operative mortality 9.8 per cent.

COMMENT

From this series of cases and from studies of similar ones, I do not believe that there should be any distinc-

All cases in this study were under the personal supervision of Dr. Gotten. Dr. Temple Fay assigned these cases of head trauma at the Jewish Hospital to the care of Dr. Gotten, which privilege made this paper possible.

tion between cases in which the skull was fractured and those in which blood was found in the cerebrospinal fluid. These conditions are only an index to the severity of injury the brain has received. It is to be noted that, in this series, eighteen of the patients with fractured skulls did not have blood in the spinal fluid, whereas seventeen of the patients with bloody spinal fluid had no fracture of the skull. This fact is emphasized to show that neither a fractured skull nor a subarachnoid hemorrhage alone can be used as the criterion of head injury. Either of these manifestations of brain trauma is sufficient to warrant hospital or bed care.

Many patients, after a severe blow to the head, have neither of these two manifestations but show symptoms of trauma to the central nervous system. This group is most often classified under the heading of "concussion."

The use of the word "concussion" as the diagnosis of brain injuries must be exercised with caution. With this diagnosis a sense of security is too quickly acquired by the physician and, as a result, serious cerebral complications may be overlooked. It has a definite descriptive meaning and should identify a definite condition. Concussion is a period of unconsciousness followed by

ternae, the ventricles or the subarachnoid space. Sometimes multiple hemorrhages may also occur in the pia mater spread to the surrounding cortex, but by far the most common pathologic changes in cases of head trauma are petechial hemorrhage with intense congestion and local edema. The petechiae are frequently limited to the subcortical white matter. This picture has been described by Cassasa,⁶ who found multiple petechial hemorrhages throughout the cortex after head injury without lacerations of the scalp, fracture of the skull or contusion of the cortex. Winkelman and Eckel have also reported microscopic changes in cases of head trauma. They found large and small hemorrhages in the brain with evidence of the onset of edema shortly after injury. Around the areas of petechial hemorrhages was complete destruction of the brain tissue. In one of their cases, hemorrhages were present throughout the entire brain, both in the cortex and in the subcortex, with attending generalized gliosis. In the smaller blood vessels in this case there was some thickening of the lining membrane cells with ischemic cell death. There seems to be sufficient evidence that even in cases of mild head trauma hemorrhage occurs with resulting areas of softening and gliosis of the entire brain.

Kymographic record showing effect on cerebrospinal fluid after intravenous injection of 50 per cent sucrose solution. From the physiology department, given dial and urethane anesthesia 0.5 Gm. per kilogram of body weight.

symptoms of injury to the nervous system. When treatment is based on this definition, attention in the series is focused on forty-nine cases diagnosed as concussion. Three of the forty-nine patients subsequently died. There was no evidence at the time of admission of a severe brain injury, but the mild injury was sufficient to precipitate complications that resulted in death. None of this group of patients had fractured skulls or bloody cerebrospinal fluid. However, their injuries were sufficient to cause marked manifestations of brain damage. It should be emphasized that among their symptoms were severe convulsions, hallucinations, mania, persistent headache, disorientation and increase in blood pressure. It is probable that all cases in which a period of unconsciousness exists should be classified under the one term, "brain contusion." Inability of the physician to find the clinical manifestations does not wash away the underlying pathologic condition.

PATHOLOGY

The gross pathologic changes of head trauma are familiar to all. They are mass hemorrhages (epidural and subdural), subarachnoid and petechial hemorrhages, lacerations of the brain and generalized edema. The pathologic changes from epidural and subdural hemorrhages produce their effect by compression of the brain.

Subarachnoid hemorrhages may be large or small. Tears in large vessels may bleed directly into the cis-

With the pathologic proof that ischemic cell death occurs in brain trauma, it may be surmised that in mild cases edema eventually becomes so severe that death ensues. In the group of four cases analyzed in the mortality report the clinical and pathologic observations were parallel. As was pointed out, in none of these cases did the initial trauma seem severe. The clinical course, however, was progressive until it terminated in death. There was no focal involvement of the brain, nor did the spinal fluid show evidence of severe injury. By deduction, one may conclude that a generalized cortical edema followed the injury and that ischemic cell death became too great for recovery.

From the pathologic changes just discussed, attention is again called to the large group of cases classified under the heading of concussion. These patients presented no evidence of fractured skull or bloody spinal fluid, though clinical signs of brain injury were evident. For example, focal and generalized convulsions, aphasia, paralysis, nystagmus, severe headache, slow pulse, increase in intracranial pressure and Cheyne-Stokes respirations occurred. Many of these patients had no initial period of unconsciousness but these symptoms developed subsequent to trauma. In three instances death ensued. The careless handling of patients with early evidence of mild trauma may result in death.

TREATMENT

Our experience previous to beginning this series had shown that better results could be gained by nonoperative treatment. Consequently, conservatism was the watchword in this series and is recommended with the following reservation: The only conditions requiring operation are subdural and epidural hemorrhages and those of compound or depressed fractures. The epidural and subdural hemorrhages comprise less than 3 per cent of the total number of cases; therefore the operative method of treatment is rarely indicated. Operation for the relief of intracranial pressure cannot be too highly condemned because anesthetic difficulties add only injury to an already traumatized brain. When these operations are performed for the relief of intracranial pressure, spontaneous rupture of the brain may occur from the removal of bone and incision of the dura. Recovery then becomes more difficult.

The recent conservative trend in the treatment of cerebral trauma, particularly as regards surgery, is familiar to all. Our results by conservative methods have coincided with those of Fay, Mock, Swift and others. These methods were given preference when it was noted that the chief underlying condition following a blow to the head was a rise in hydrostatic pressure

the first three or four days this amount was gradually increased if the physical condition improved. Limitation of fluids has its chief effect by reducing brain volume, but one must be careful to prevent dehydration of too severe degree. This is manifested by a rise in pulse rate and an elevation of temperature. Sufficient fluids should always be given to prevent this condition.

The other method of controlling intracranial pressure is by use of hypertonic solutions. Dextrose was used in most of our cases, but sucrose⁷ has recently been substituted and found to be more satisfactory. A number of experimental and clinical papers have previously pointed out the demerits of concentrated dextrose therapy. Following the injection of dextrose there was found to be a secondary rise in intracranial pressure (Sacks and Wassermann). Bullock, Kinney and Gregersen⁸ found that with sucrose this secondary rise did not occur. Their results were confirmed in experiments on dogs in the physiology department of Temple University. The illustrative kymographic record shows the prolonged lowering of intracranial pressure as well as the extraordinary stimulation of urinary output in one of these experiments. The amount of fluid excreted was far in excess of the total amount of administered fluids and there was no toxic

ent of Temple University Hospital. This chart represents one of a series of similar experiments with sucrose. A female dog weighing 7.5 Kg. was

with extravasation of fluid into the perivascular spaces. This resulted in stasis of cerebral circulation and led to anoxemia. Another factor in raising the intracranial pressure is the mechanical blocking of the cerebrospinal fluid system due to hemorrhage into this system. The combined results of the physiologic changes is congestion and edema of the brain. There is little doubt that edema of the brain was present in more than 50 per cent of our cases and free blood was found in the fluid of 65 per cent of them.

Our subsequent treatment of these cerebral injuries was individualized as much as possible. In each case the treatment given depended on the severity of the injury manifested by the focal or general neurologic condition. A spinal puncture was done as a routine to determine the pressure changes and the degree of hemorrhage. If the pressure was within the normal limits or only slightly elevated, no further punctures were performed. If the spinal fluid pressure was increased to an appreciable degree, fluid was removed until the pressure was brought to a normal level. Subsequent spinal punctures were performed until the normal balance could be maintained by limitation of fluids.

Moderate limitation of fluids was the routine, but the amount varied with the patient's general condition and the spinal fluid pressure. As a rule, between 900 and 1,200 cc. of total fluid was allowed daily. During

effect. Following these experiments, sucrose was administered in 50 per cent solution in cases of head trauma with very satisfactory results. Hypertonic solutions have their greatest value during the period of shock and acute edema, but care must be taken to prevent depletion of body fluids. After the acute period of trauma is over the patient is kept on moderate limitation of fluid for a period of months, depending on the severity of the injury and on the post-traumatic symptoms. Phenobarbital in divided doses is also given for a period of from one to two months. The use of a sedative and some limitation of fluids are necessary in the prevention of post-traumatic symptoms. This phase of the subject has been fully discussed by other authors (Fay).

The most important single factor in the treatment is nursing care, particularly in the receiving ward. Nearly all the patients in our series suffered from some degree of shock. Proper nursing through the shock period is essential for recovery from the immediate effects of trauma. On admission patients were sur-

7. Eli Lilly & Co. supplied the sucrose solution used in the experiments; Dr. Melvin Oppenheimer and Dr. Gotten carried them out. Since this work was done an article has appeared in the literature on the clinical use of sucrose in brain injuries (Hahn, E. V.; Ramsay, F. B., and Kohlstaedt, K. G.: Clinical Experience in the Use of Sucrose Instead of Dextrose in the Osmotic Therapy of Increased Intracranial Pressure of Acute Brain Injury, *J. A. M. A.* 108: 773-736 [March 6] 1937).

8. Bullock, L. T.; Kinney, R., and Gregersen, M. L.: The Use of Hypertonic Sucrose Solution to Reduce Cerebrospinal Fluid Pressure Without Secondary Rise, *Am. J. Physiol.* 109: 17 (July) 1934.

rounded with external heat in the form of warm blankets and hot water bottles. Hypertonic solutions were administered to restore blood pressure. No attempt was made to repair lacerations of the scalp at this time. Sterile wet dressings were applied and further attention to the wound was delayed until after recovery from shock. Mild sedatives in the form of soluble phenobarbital were given to combat restlessness. X-ray examinations and spinal punctures were at all times deferred until shock was past, because of the danger of exposing the patient's body.

SUMMARY

In a series of 141 consecutive cases of head trauma admitted to the Jewish Hospital, Philadelphia, from May 1933 to May 1936, all patients having a fractured skull, subarachnoid hemorrhages or a period of unconsciousness of more than five minutes are included. There were fifteen deaths, giving a mortality rate of 10.6 per cent. Seven of the patients who died were over 60 years of age. The mortality of patients over 60 years of age was approximately 30 per cent. The mortality of patients under 20 years of age was approximately 5 per cent. The clinical observations on four fatal cases were analyzed. These patients died from what was apparently an ischemic cell death. Only seven patients were operated on. Four recovered and three died. In every case operation was postponed until all other methods of therapy had been considered. Operations were performed only when a mass hemorrhage was suspected.

Particular attention is called to cases presenting on first examination evidence of very mild cerebral injuries. Subsequent examinations showed that mild trauma frequently brings on serious complications in both young and old patients. These complications are manifested by convulsions, transitory paralysis, aphasia, severe

vertigo, persistent headache and the like. The pathologic basis for these observations is probably multiple petechial hemorrhages throughout the entire brain.

Conservatism in treatment is important. The patient is given preliminary treatment for shock and then a thorough neurologic examination. Routine lumbar punctures are done only to relieve any increase in intracranial pressure. Hypertonic dextrose solution is not advocated. Clinical experiments are being carried out with sucrose solution for the reduction of intracranial pressure, as it does not cause a secondary rise in intracranial pressure.

CONCLUSIONS

1. The most important single feature in treatment is good nursing care, with particular reference to treatment in the receiving ward.

2. The age of the patient is the greatest factor favoring recovery from head injury. The younger the patient, the higher the percentage of recovery.

3. Complications occurring in what appears at first to be mild injury should receive particular attention.

4. Continued conservatism in treatment is strongly advocated, operation being avoided whenever possible. The reduction of intracranial pressure by conservative methods available in every hospital is recommended, such as limitation of fluids, magnesium sulfate and lumbar puncture.

THE EXCEPTIONAL REQUIREMENT OF INSULIN AND SALT SOLUTION IN DIABETIC COMA

HOWARD F. ROOT, M.D.

AND

J. E. F. RISEMAN, M.D.

BOSTON

Although the treatment of major emergencies such as profound diabetic coma cannot be standardized, it must be directed by consideration of fundamental principles. The first is that insulin must be given early enough and in sufficient doses to produce the desired effect, regardless of the number of units. The second is that intense dehydration with fall of blood pressure and consequent anuria must be combated by replacement with liquids containing electrolytes in sufficient quantity to restore blood volume and electrolyte balance. A sufficient dose of insulin may be as little as 30 units or it may be from 500 to 1,200 units. The essential thing is that it shall bring about a restoration of normal carbohydrate metabolism as indicated by a falling blood sugar and a rising carbon dioxide combining power of the blood plasma. Patients treated early in the course of coma will require smaller doses; patients treated after a long period of neglected treatment will require correspondingly larger doses. With regard to the administration of fluid, in general, most patients in diabetic coma will not require more than from 4,000 to 5,000 cc. of salt solution including the amount given intravenously and under the skin in addition to the small amount which can be given by mouth. However, there are exceptions which require an individualization of dosage and the use of such large quantities as would seem dangerous to physicians unfamiliar with these extraordinary cases. The following cases are reported to illustrate the use of 1,320 units of insulin in profound coma and the administration of 11,000 cc. of salt solution in the course of a few hours with successful results:

REPORT OF CASES

CASE 1.—A woman, aged 31, entered the Beth Israel Hospital April 22, 1937, in profound diabetic coma. For at least two months she had been losing weight and strength and had a great increase in appetite. No medical examination or urine test had been made since the age of 5 because of a devotion to a non-medical cult. For one month she had been in a rest home and for four days she had had no appetite. Two days previously she had been short of breath and she vomited the day before. On the morning of admission she was found unconscious. Catheterization in the hospital produced 30 ounces (900 cc.) of urine containing 4.2 per cent of sugar and 4 plus diacetic acid. The blood sugar was 1,194 mg., carbon dioxide combining power was 3 volumes per cent, nonprotein nitrogen was 55 mg. per

From the George F. Baker Clinic, New England Deaconess Hospital and Beth Israel Hospital.

hundred cubic centimeters. She was given 80 units of insulin. No more urine was secreted, so that the actual time of onset of anuria was uncertain. During the next two hours with anuria, the blood pressure steadily fell to 60 systolic, 38 diastolic, and at times during the next half hour she was pulseless. The rectal temperature was 94 F. The extremities were cold and mottled. The eyeballs were so soft that a reading with a tonometer could not be obtained. In the face of the anuria and the falling blood pressure, despite 4,000 cc. of fluid given subcutaneously, it was decided to administer saline solution constantly by means of an indwelling cannula tied into a vein in the leg. During the next eight hours she received 8,000 cc. of salt solution intravenously, in addition to the 4,000 cc. of salt solution given subcutaneously. The accompanying table summarizes the changes in the blood chemistry, the insulin dosage and the amount of fluid administered.

The plasma chloride value was 568 mg. per hundred cubic centimeters seven hours after the administration of salt solution was begun; the nonprotein nitrogen rose to 67 during the first few hours and returned to normal only after eight days. Incidentally, the white blood count was 28,500. The initial red blood count of 5,750,000 fell to 3,950,000, where it remained for two months. For nine hours while she was anuric and the extremities were cold, four nurses massaged the extremities and massaged the fluid given under the breasts to make sure of its absorption. Gastric lavage gave 250 cc. of thick, yellow, dark fluid. Evidence of pitting edema did not develop in spite of the administration of 12,000 cc. of liquid in eleven hours. It must be remembered that the patient was absolutely untreated, and for probably four months she had been breaking all the rules that would ordinarily be imposed on a diabetic patient and had been allowed to go as far in coma toward death as it is possible for any one to go and recover. We feel sure that the patient would have died had the usual routine amounts of liquid or much smaller doses of insulin been given.

Four months after discharge, she gave up treatment. Within three months mild coma again occurred with recovery. Yet this was so mild a case that 8 units of insulin a day kept the urine sugar free and blood sugar normal with good dietary control.

CASE 2.—A woman, aged 25, a kindergarten teacher, was seen by one of us (H. F. R.) through the courtesy of Dr. F. G. Brigham and Dr. Earl Lehnher on Dec. 9, 1937. The diabetes had begun in September 1927, and she had taken insulin since 1928. Protamine zinc insulin had been given her previous to admission; up to December 4 she was taking 50 units of protamine zinc insulin once a day and was in good condition. December 7 she felt as if she were getting a mild attack of grip; during the night, from 10 o'clock on, she vomited "every ten minutes." At first there was no pain, but the rest of the day she had severe pain in the back. The next morning, December 8, morphine was given for the relief of pain, dyspnea and restlessness. That afternoon she was found unconscious. On admission at 5 p. m. December 8, she had typical Kussmaul respiration and acetone breath and, while apparently unconscious, she could be roused by vigorous stimulation. The eyeballs were soft, the urine sugar was 2.8 per cent, and 3 plus reaction for diacetic acid was found. The blood sugar was 620 mg. per hundred cubic centimeters and the carbon dioxide combining power of the venous blood was 3 volumes per cent. She was immediately given 40 units of insulin and in the next seven hours received a total of 240 units of insulin. Nevertheless, the blood sugar rose to 870 mg. per hundred cubic centimeters, and it was evident that her condition was not improved, since the blood pressure had fallen from systolic 108 to 80 at 11:30 p. m., and the amount of urine obtainable at 9 p. m. was measured only in drops. In fact, at 11 o'clock no urine was obtained. By 3 a. m. December 9 she was pulseless. At this time, since she had been anuric for five hours, it was decided to increase the amount of fluid administered, and a cannula was therefore tied into a vein in the leg and constant infusion of physiologic solution of sodium chloride was begun. A gastric analysis on admission yielded nearly a quart of tarry, black fluid.

She received a total of 11,660 cc. of physiologic solution of sodium chloride, of which, 6,860 cc. was given by the intravenous route in a period of ten hours. The subcutaneous fluid previously given had contained dextrose. The total amount of

insulin was 850 units. In this instance, in spite of the administration of 240 units of insulin and 4,800 cc. of fluid, in which was included 3,500 cc. of 5 per cent dextrose solution, the patient became anuric and pulseless and the blood sugar rose to 1,000 mg. per hundred cubic centimeters. When, at this point, the use of insulin in doses of 100 units and of constant intravenous infusion of salt solution was begun, the blood sugar fell steadily to 230 mg. per hundred cubic centimeters at the end of thirteen hours, the secretion of urine returned and the blood pressure rose. The amount of blood and chloride lost from the stomach was not estimable except from the patient's description of the frequent vomiting and the tarry matter obtained from the stomach and the further fact that a rather marked anemia developed, so that the red cells six days later numbered 2,990,000 and the hemoglobin was 56 per cent. Under treatment with iron and liver extract the anemia has improved, so that on Jan. 12, 1938, the blood count was normal and the hemoglobin was 80 per cent.

The first plasma chloride four hours after admission was 557 mg. The next day the plasma chloride had risen to 682 mg. and this value had returned to 619 mg. December 11. Undoubtedly to some extent the anemia was due to a dilution effect, but it is true that no visible or palpable edema ever developed. The

nonprotein nitrogen of the blood had risen from 60 to 69 mg. per hundred cubic centimeters eight hours after admission but had returned to 38 mg. two days later. January 12 the blood sugar was 130 mg. per hundred cubic centimeters and the nonprotein nitrogen was 28 mg. Her weight on that day was 135 pounds (61 Kg.) as compared with 141 pounds (64 Kg.) on Dec. 4, 1937.

COMMENT

These cases illustrate the disadvantages of using dextrose solution during the early stages of coma when the patient's carbohydrate metabolism is so disordered that utilization of the dextrose is impossible. Thus, in each case the administration of dextrose led to the difficulty of deciding whether the high and rising blood sugar was due to increasing severity of the coma or to the administration of the dextrose. During severe and uncontrolled diabetic coma, dextrose is to be regarded as a poison. In such cases the use of dextrose solutions may be the deciding factor in producing the final stage of anuria. When, however, sufficient insulin has been given to bring about the control of carbohydrate metabolism, dextrose solution given either subcutaneously or by vein may be the safest and easiest way of administering food.

In the first case, a total of 8.2 Gm. of sodium bicarbonate was given in the salt solution at a period beginning six hours after hospital admission. It must be confessed that this was an extremely faint-hearted use of sodium bicarbonate in an amount which could not possibly have had any effect on the condition. Patient

2, when anuric, was given 60 cc. of 10 per cent salt solution just after the administration of constant intravenous infusion had been begun. Possibly this contributed to relief of the anuria.¹

The use of 1,280 units of insulin in case 1 between 11 a. m. one day and 4 a. m. the next day, a period of seventeen hours, to reduce the blood sugar from 1,194 mg. to 136 mg. per hundred cubic centimeters (value obtained twenty-seven hours after first dose) may seem an unnecessarily large amount. One may take for comparison other conditions in which large amounts of insulin have been used. In the case of a physician with hemochromatosis, 1,600 units of insulin a day was given regularly.² In such an instance there is a clear indication of the reason therefor. When the liver is so severely damaged as seriously to reduce the power of removing sugar from the blood in order to store glycogen, it is not strange that the amount of insulin required becomes high. Similarly, in acute hyperthyroidism complicating coma one deals with a disturbance affecting liver function, and in one such case 800 units of insulin was required. Although the average amount of insulin given in the first twenty-four hours of diabetic coma has tended to rise in the interim between 1923 and 1936, during the last eight years the average has varied between 200 and 252 units.³ However, in the 338 attacks of diabetic coma occurring in 275 patients at the New England Deaconess Hospital a dose of from 500 to 800 units of insulin in the first twenty-four hours has by no means been rare. In the first case here presented the fall of blood sugar was gradual, the urine became sugar free at the time the blood sugar reached 136 mg. and at no time did hypoglycemia develop. Indeed, a few hours later that same day the blood sugar on two different occasions was 218 and 326 mg. There is no justification for feeling, therefore, that the amount of insulin given was excessive or that it was lost in the urine, because it must be remembered that the patient was anuric during the first eight and one-half hours of treatment. Similarly, during the period when the greater part of 800 units was given, patient 2 was anuric and therefore no suspicion can be raised that so much insulin failed to be utilized because it was lost in the urine. Here also the fall in blood sugar, once a sufficient amount of insulin was given was steadily downward, until the value of 230 mg. was obtained twenty-three hours after admission. At this time the urine also became sugar free and a single specimen of urine obtained every hour thereafter was sugar free for twenty-four hours, and during this period it was possible to give the patient much needed food with the confidence that it would be metabolized. Since February 1929 in fifteen attacks of diabetic coma during the first twenty-four hours of treatment at the Deaconess Hospital from 510 to 1,020 units of insulin has been required. In this group occurred three deaths. An aged woman who received 1,020 units died of cerebral hemorrhage that had been present before admission; a young man died of acute hemorrhagic pancreatitis; a woman who received 780 units died with anuria seven hours after admission to the hospital, an attack which we would now treat by the methods here advocated.

Fluid and Electrolyte Requirements.—In only three of 338 attacks of diabetic coma have we thus far used

more than 8,000 cc. of fluid, including subcutaneous and intravenous, within twenty-four hours of admission. In retrospect it has seemed quite evident that we have lost patients in the past with circulatory collapse and anuria because of failure to give sufficient fluid and electrolyte quickly enough. Tremendous variations in the rapidity and severity of diabetic coma occur in different individuals with different types of diabetes. Fundamentally, diabetic coma is due to a lack of control of diabetes and a loss of the power to metabolize carbohydrate and fat normally. A breakdown of fat acids results in large quantities of ketone bodies. A certain portion of these bodies is excreted as free acid and other portions are neutralized and excreted. With excessive ketone production, neutralization of the acid is accomplished not merely by means of ammonia but by the withdrawal of fixed base, chiefly sodium. This is accomplished by a reduction in the base of the blood and a reduction of the total salt and the total electrolyte concentration in the body fluid. The fluid is excreted with dehydration, a reduction in the fluid volume of the body and a further loss of base. The end results are (1) hemoconcentration and dehydration; (2) loss of both base and chloride in the body; (3) reduction of the plasma carbon dioxide combining power; (4) the shift of the p_H of the blood toward the acid side. In diabetic coma of only a few hours or a few days' duration, with a patient whose diabetes is not fundamentally severe, the amount of insulin and the amount of fluid and base required may be moderate. As a rule with most of our patients from 4,000 to 5,000 cc. of salt solution has been ample, but the cases reported here show clearly that there are exceptions in which vastly more aggressive treatment is required.

Causes for Diabetic Coma of Unusual Severity.—In addition to the usual causes such as infection, breaking the diet and omission of insulin, one must stress delay in diagnosis and treatment as the chief factor in producing unusual severity and fatal termination of coma. These two cases illustrate two causes not often emphasized. One patient, with mild diabetes, was a practitioner of a cult and neglected symptoms until she was actually found unconscious. This was not a case of insulin resistance, but merely of neglected treatment. The other patient presents a more tragic failure: when she was in pain with serious acidosis, prior to being seen by any physician here mentioned, morphine was given, the worst possible medication for a patient in whom the diagnosis and the treatment are at all uncertain. Morphine and diabetes are sworn enemies under such circumstances.

Indications for Constant Intravenous Infusion of Saline Solution in Large Amounts and the Use of Insulin Above 500 Units.—In the future the following factors will again lead us to employ these aggressive methods of treatment:

1. Clinically, a history of prolonged acidosis and lack of diabetic control, unconsciousness for more than six hours and repeated vomiting.

2. On examination, soft eyeballs, dry, cold and mottled skin, a rectal temperature below 97 F., systolic blood pressure below 90 mm. of mercury, gastric dilatation with tarry contents and, finally, diminishing urinary secretions.

3. Laboratory indications of severe coma such as a carbon dioxide combining power of below 10 volume per cent and a blood sugar of over 700 mg.

GENTIAN VIOLET AS A THERAPEUTIC AGENT

WITH NOTES ON A CASE OF GENTIAN VIOLET TATTOO

RICHARD L. SUTTON JR., M.D.

Instructor in Dermatology, University of Kansas School of Medicine
KANSAS CITY, MO.

New and Nonofficial Remedies, 1937,¹ gives the information that the medicinally interesting derivatives of triphenylmethane and its homologue tolyldiphenylmethane are those which result from the introduction of amino groups forming pararosaniline, $(\text{NH}_2\text{C}_6\text{H}_4)_3\text{COH}$, and rosaniline, $(\text{NH}_2\text{C}_6\text{H}_4)_2(\text{CH}_3\text{NH}_2\text{C}_6\text{H}_3)\text{COH}$.

On treating rosaniline with hydrochloric acid, the hydroxyl of the carbinol group is split off, permitting the formation of the quinoid group, thus forming a typical dye known as fuchsin, $\text{NH}_2\text{C}_6\text{H}_4\text{CH}_3\text{NH}_2\text{C}_6\text{H}_3\text{C}:\text{C}_6\text{H}_4:\text{NH}_2\text{Cl}$. The red color of pararosaniline chloride or fuchsin is changed to violet by the entrance of a methyl group in the amino groups, the intensity of the violet color increasing with an increasing number of methyl groups. Thus, there are the closely related gentian violet, crystal violet and methyl violet. Gentian violet is a mixture of pentamethylpararosaniline chloride and hexamethylpararosaniline chloride; by some it is defined as a mixture of methyl violet and crystal violet. . . . It seems likely that in therapeutics . . . the one most easily obtained in pure form (crystal violet) will be the one most used. . . . Gentian violet was introduced as an antiseptic by J. Stelling in 1890. . . . Gentian violet occurs as a dark green ("bronze") powder or greenish glistening pieces having a metallic luster. It is soluble in water (1 in 10), alcohol or chloroform, insoluble in ether.

A use mentioned here, not pertinent to this article, is in the treatment of infection with *Strongyloides*; 0.03 Gm. may be given in enteric-coated capsules. Gentian violet is insoluble in petroleum fractions; "pyoktanin" is the same substance with a proprietary name.²

Hyde and Montgomery³ state that "pyoktanin blue is employed in aqueous saturated solution as a parasiticide . . . valuable as a local and painless application in circumscribed patches of weeping or scaly eczema, in many of the ulcerating syphilodermata, in lupus and in ringworm."

Churchman and Michael⁴ reported in 1912 that the dye kills or stops the growth of most gram-positive micro-organisms. Churchman and Russell⁵ in 1913 reported the effect of gentian violet on protozoa and tissues growing in a culture medium. They found tissues unharmed by a dilution of 1:100,000, a strength in which gram-positive organisms were inhibited (diphtheria, *Staphylococcus aureus*, gonococcus and others). They found 10 mg. per kilogram of body weight harmless to rabbits. This dose given intravenously instantly stained all mucous membranes purple, but the stain disappeared. They estimated the concentration in the rabbit's tissues at 1:70,000. They gave an infant with staphylococcic septicemia 5 mg. per kilogram, a dose which proved toxic and depressant

to the white blood cell count, which fell from 20,000 to 10,000 in a few hours. Further doses of 3 mg. per kilogram were well tolerated and were attended by prompt improvement and cure.

In 1920 Churchman⁶ described the bacteriostatic action of gentian violet in the treatment of wounds. While its selective activity was not so clear cut as in vitro, nevertheless there appeared to be resistance on the part of infections due to gram-negative bacteria and response in those due to gram-positive ones. Two amputation stumps carrying diphtheria bacilli healed, and four others in which diphtheria bacilli were not present also healed. Adjacent dermatitis responded promptly. Churchman used the dye in Vincent's gingivitis with results that seemed very satisfactory. He gave a bibliography of his own work complete to 1920.

Farley⁷ (1920) found that a dilution of 1:250,000 of gentian violet in Sabouraud's medium inhibited the gram-positive bacteria but allowed the free growth of fifty-one strains of fungi cultivated from cutaneous tissue. As a restrainer, it was used in the isolation of about twenty strains of pathogenic molds with apparently good results. Mitchell⁸ commented on this work as follows:

The use of 95 per cent alcohol or flaming the tissue seems all that is required inasmuch as all gram-positive bacilli do not grow luxuriantly at room temperature; the most troublesome organism is *Penicillium*, which in the experiment of Farley invariably was found to grow through all concentrations, even 1:1,000; therefore the method is of least value as a restrainer when most needed.

In 1921 Churchman⁹ described the use of gentian violet in the sterilization of closed cavities, especially in gonorrheal arthritis, where great benefit was obtained.

Smith and Casparis¹⁰ (1923) found that gentian violet will inhibit the growth of some staphylococci in a dilution of 1:1,000,000. Young and Hill¹¹ (1924) used gentian violet in a few cases of septicemia. They found that an intravenous dose of 20 mg. per kilogram of body weight killed rabbits in five hours. One child was given 8 mg. per kilogram and lived, being cured, they believed, by further doses of 5 mg. per kilogram. An adult given 6.8 mg. per kilogram became severely nauseated, with vomiting and diarrhea. They decided that 5 mg. per kilogram is a drastic dose but justified by the extremity of the disease, while smaller doses were well tolerated. A person weighing 50 Kg. (110 pounds) can safely receive 0.25 Gm. intravenously, and he therefore cannot be harmed by (non-allergic) absorption of 25 cc. of 1 per cent solution painted on his skin. This amount will paint a surprisingly large area.

The utility of the dye was by this time common knowledge, THE JOURNAL having carried four important articles regarding it between 1920 and 1924. Dr. Elmer Twyman, surgeon, introduced it into the daily practice of Dr. R. L. Sutton Sr.; Dr. Samuel Sweitzer of Minneapolis has long been an enthusiast, having so

been cured of his own impetigo, and Oliver S. Ormsby¹² in his textbook mentioned pyoktanin through two editions to 1921, adding in the fourth edition (1934) that pyoktanin is methyl violet. It may be said that there was a wave of popularity about 1920 to 1925 and that the popularity is again decidedly in its ascendancy.

Gomez-Vega¹³ in 1935 reported the testing of eighteen chemicals with regard to their mycostatic properties. She found the growth of all strains of *Monilia* inhibited in a dilution of 1:100,000 while most of the strains of *Torula* and all the strains of *Saccharomyces*, *Epidermophyton* and *Trichophyton* grew in a dilution of 1:400,000 but not in 1:100,000. A patient with monilial paronychia involving five fingers, long resistant to many types of treatment, was cured in two months by using "the standard gentian violet solution in the Gram stain" (anilin-water gentian violet). Crystal violet, she concluded, and its compounds gentian violet and methyl violet, showed marked specific action or selective activity in vitro on fungi of the *Monilia* and *Torula* genera, while the other fungi tested withstood five times the concentration.

Percival¹⁴ of Edinburgh reported in 1936 the value of aqueous solution of gentian violet in the treatment of seborrheic dermatitis, which is remarkably severe in Scotland and the Scandinavian countries. Before my visit to the Royal Infirmary in 1932 the alcoholic solution had been customarily used, and I pointed out to my friends that there is no irritation when the aqueous solution is employed. Alcohol caused oozing to become even more severe and precluded the use of the dye oftener than a few applications per week, and pastes had to be used between times.

Florance¹⁵ of Sydney testified to the usefulness of the aqueous solution of gentian violet, which he learned from Percival at the Royal Infirmary in 1934, in seborrheic dermatitis of the scalp, impetigo, impetiginized eczema, paronychia and eczematoid ringworm of the hands and feet. It can be used safely in or about the mouth, he says, and on babies' faces, and there is no ill effect from absorption from large areas painted with the dye. He considers it of comparatively little value in more deeply seated pustular conditions, such as furunculosis, sycosis and Bockhart's impetigo, its action being too superficial. He states that the color of the dye is a great disadvantage but that "patients, tired of ineffective ordinary treatment, are usually quite willing to entail this disadvantage for the sake of ultimate improvement."

Many writers have complained that the color is too objectionable to permit of application on exposed surfaces. This is an inadequate argument in my experience, which coincides with Florance's;¹⁵ the color washes off or is exfoliated from the skin within a week. It is damaging to clothing but washes out eventually, especially if encouraged with alcohol or bleached with chlorine water. It has uniformly been my experience that if the patient is forewarned of the staining, is advised to use cheap clothing, bedclothes and towels, and gets the promised relief there are few complaints. Sometimes a little salesmanship is required. The results justify it. In the hospitals the housekeeper is

pacified by a request that the nurses use old linens; and the damage is no greater than when crude coal tar, chrysarobin or permanganate are used—indispensable medicines, all of them.

Gentian violet is cheap, an ounce (30 Gm.) of the crystals costing less than \$1. An ounce makes 3 pints (1.5 liters) of 2 per cent solution with water by practical if not meticulous arithmetic. This is a suitable strength for topical application.

I have used it in the mouth in the treatment of Vincent's angina with great satisfaction. One should swab all involved areas, then offer the patient a mouthful of tepid water to be promptly spit out. This so dilutes the unattached dye that the lips are not stained. The clothing should be protected, of course. The mucous membranes are dyed a deep purple, which washes off within a day with saliva, which is swallowed with safety. The taste is preferable to that of silver nitrate.

In topical application my experience has been that gentian violet does not irritate and is nontoxic. Florance¹⁵ protects himself by saying "It is of low toxicity and except in a few cases of idiosyncrasy to the dye (which may occur with the use of any chemical, however dilute) it can be used on any skin." He gives no instance. I have never seen intolerance; I have never read of it elsewhere. If it occurs, it is exceptionally rare, rarer than intolerance to the weak phenol dilution so nearly universal in dermatologists' prescriptions. If a case of sensitivity to gentian violet should be seen it would be worth reporting. I prescribe no other agent with less fear of irritation. This is a real asset in a drug intended for common use, for whenever a patient of mine unpredictably proves sensitive to my medicines he doesn't accept an explanation and he shows no interest in allergy; he hunts up another doctor.

From my experience, I vouch for the well known external uses of gentian violet. In infectious eczematoid dermatitis it can effectually be combined with wet applications of 1:5,000 mercury bichloride. The superimposition of wet dressings (made of old, clean turkish or hand towels) allays the discomfort of dryness, allows deeper penetration of the dye and destroys by mercury those bacteria which do not yield to gentian. I know of no more effectual means of combating that disease.

Krinsky¹⁶ (1934) reported the utility of gentian violet in the treatment of ulcers of the leg; he sprayed the solution on repeatedly so as to allow the formation of a thick crust. Infection decreased, the area shrank, granulations appeared and healing followed. Thurmon and Chaimson¹⁷ (1937) commend the gentian violet treatment of leg ulcers. I agree with their approval.

Reid's¹⁸ recent essay on the treatment of ulcers is commendable and noteworthy. He stresses the concept that the cure of a wound is a problem of tissue culture and requires more than asepsis and antisepsis. One must prevent and eliminate debris and necrosis; one must immobilize; one must have good blood supply (in leg ulcers this generally implies elevation), and antiseptics must be mild. To dermatologists it is enlightening and edifying to find that surgeons are finally coming to such sensible views. They are frequently enough guilty of expecting the ingredients of

a salve to heal the sore, whereas in truth the best the salve can possibly do is to let the tissues heal themselves. Surgeons frequently light on the time-honored dermatologic practice of applying wet dressings to ulcers instead of petrolatum mixed with assorted chemical contaminants and go to press with enthusiastic acclaim over allantoin, thiocresol, insulin¹⁹ solutions, and what not. If one excised a circular disk of skin 2 cm. across from the shin of a healthy young athlete and promptly hospitalized him for the duration of the healing, about twenty-four days would be required for granulation and epithelization, and nothing under the sun could hasten it, but many things, indeed, could slow it down. The use of gentian violet in the treatment of ulcers is very satisfactory, for it is nonirritating and efficiently bacteriostatic and does not interfere with the proliferation of tissue cells on which the healing is absolutely dependent; if allowed to dry after repeated paintings, it forms a crust which fairly immobilizes the lesion.

In the treatment of burns, Ovens,²⁰ among others, has found its advantages over tannic acid to be that (1) the eschar is flexible, (2) it does not contract so much, (3) infection beneath it is easier to detect than beneath the tougher eschar of tannic acid and (4) the aqueous solution keeps indefinitely and does not require to be made up fresh.

In infections more deeply seated than impetigo and eczematoid staphylococcic disease, gentian violet has a valuable and practical use in the prevention of auto-inoculation. A condition well described by the MacKenna²¹ under the title "Multiple Boils in Children" (which they attribute to infection of the sweat glands for no sound reason) manifests itself as numerous, painful, red and bluish red papules and dome-shaped nodules, some of which soften and discharge thin pus; they are grouped but spread by autoinoculation, starting commonly on the back of the head or on the buttocks—a well defined clinical picture. I have treated two such examples by the repeated widespread application of gentian violet in watery solution, which promptly stopped the inoculation of new lesions while the old ones, let alone, underwent their course of absorption, or of softening, discharging and healing.

The U. S. Dispensatory,² twenty-first edition, quotes Klein²² as having found gentian violet of value in the treatment of hoof and mouth disease.

Dr. Sherwin Mella, my colleague, finds it possible to stop the pustulation of a smallpox vaccination promptly by the application of gentian violet, so diminishing the scar and foreshortening the duration of discomfort. This may have significance in the management of variola, which is nowadays so rare that I have had no opportunity to test it.

The dye is commonly used by topical application, which is allowed to dry. This is effectual in most secondarily infected dermatoses and in those primary dermatitides due to gram-positive organisms. I have not seen mentioned my method of application with superimposed wet dressings (1:5,000 mercury bichloride; 1:500 aluminum acetate; 1:3,000 potassium permanganate—these are compatible; acid fuchsin¹ is

not). And I have not seen previous mention of gentian violet solution used as a soak or bath, which seems greatly to enhance its penetration:

CASE 1.—Dr. K., aged 60, has had a dermatomycosis of the hands for twenty years. He used a fluoroscope in setting fractures for many years. The dermatitis, irregularly flaring with vesicles, bullae and secondary infection, while dry, fissured and scaling in the intervals, was treated by roentgen rays from 1932 to 1935. In 1935 the right hand was amputated because of roentgen necrosis and infection of the tendon sheath. The left hand, now telangiectatic and studded with keratoses, inelastic and oozing in patches, promptly vesiculates when any ointment is applied, no matter what the chemical content; I have tried many. There seems to be an actual local hypersensitivity to peruvian balsam. Wet applications including 0.25 per cent silver nitrate, 1:3,000 potassium permanganate, 1:5,000 mercury bichloride, 1:500 aluminum acetate, weak saponated solution of cresol and other soaks have been experimented with but have given no satisfaction. The feet have been treated concurrently, for fungi may be saprophytic and give little clinical evidence of their presence on the feet (especially in the nails) and yet cause disease of the hands which will not heal. I applied gentian violet by swabbing twice a day, and there was improvement. I advised the soaking of the hand in 0.5 per cent gentian violet in water for thirty minutes three times a day. This stained the entire epidermis very much more deeply and uniformly, and improvement was immediate. The soaking was discontinued after three days of energetic staining, and topical application was resumed on circumscribed areas where dermatitis and roentgen keratosis coincided. The progress toward healing is the most satisfactory the patient has experienced.

Gentian violet may be used with good effect in pruritus ani and pruritus vulvae, a fact well known to too few physicians. Itching in these locations is more commonly due to Monilia or other fungi (Epidermophyton), with superimposed medicinal and traumatic irritation, than to any other causes. I agree with Hesseltine²³ (1933), who finds that diabetes causes pruritus because dextrin encourages the growth of mycotic organisms. Plass, Hesseltine and Borts²⁴ have shown that monilial infestation of the vagina is commonplace, and frequently asymptomatic, and occurs in children, virgins and senile women as well as in parous ones. The disease, they found, tends to undergo spontaneous relief, but it may become chronic, with recurrent irritation over a period of months or years. Menstruation has the same temporary beneficial effect on the course of the infection as does delivery in cases associated with pregnancy. They found the local application of 1 per cent gentian violet the best treatment, although alkaline douches may help. They believed that infantile oral thrush may result from infection in the birth canal. Popoff, Ford and Cadmus²⁵ described a case of monilial vulvitis in pregnancy. They quoted Le Baye's summary of the types of vulvovaginal moniliasis:

1. Creamy vaginitis resembling oral thrush with painful and reddened mucosa.

2. Creamy vulvitis, with considerable discharge, not much redness or inflammation, with or without a small amount of intertrigo, which characteristically consists of small, grouped, shallow vesicopustules.

3. Ulcerative vulvitis, severe, superficially ulcerated, with pain, lymphangitis and inguinal adenitis, possibly with mycotic infection of the bladder.

25. Popoff, N. W.; Ford, Francis, and Cadmus, W. H.: Mycotic Vulvovaginitis, *Am. J. Obst. & Gynec.* 18:315 (Sept.) 1929.

4. Pseudoleukoplakic vulvitis, in which the mucosa is whitish and opaque, crusts are hard to remove, but no wrinkling, papillomas or hyperkeratosis exists.

5. Eczematoid vulvitis, with vesicopustular inflammation consisting of small punctiform erosions, spreading and resembling intertrigo.

6. Mycotic pruritus of the vulva, with few erosions, perhaps, and little discharge, diagnosable only by smear and culture (and by therapeutic response, I think).

7. Vesiculopustular cutaneous form, manifesting involvement principally of external teguments with small vesicopustules, the vesicular stage being brief.

8. Cutaneous intertriginous eczematous form, which is intertrigo-like, with or without Monilia in genitocrural plica, spreading to the pubis, anal region and medial surfaces of the thighs but with little visible involvement of the vulva.

I have seen forms in the male analogous to Le Blay's types 4, 5, 6, 7 and 8 (excepting the creamy discharge, which is pus plus mucus from the cervix glands) involving the inguinal, pudendal and perianal regions. They respond to similar treatment.

I would add to Le Blay's list, on the basis of my own observations:

9. Inconspicuous vaginitis with disseminated cutaneous involvement, patches of intertriginous dermatitis with small vesicopustules, not amenable to lasting therapeutic effects until the vaginal infestation has been treated properly.

Gentian violet tattoo, visible as a purple stain at the periphery of the scar resulting from the cautery excision of a basal cell carcinoma of the nose of a white woman, aged 79.

10. Moniliids, often consisting of patches of tiny, deep-seated vesicles, which may absorb and result in superficial scaling or which may constitute an inflamed and oozing eczematous dermatitis.

These additions cannot make a claim for originality, as study of such articles as Shel mire's²⁶ and Hopkins's^{26a} on thrush infections and Sulzberger's²⁷ on fungus immunology will reveal. Flandin and his associates²⁸ recently reported a dyshidrosiform leuroides on the hands from monilial infection of the feet. It is commonplace to cure pompholyx of the hands by treating tinea of the feet when the pompholyx is a trichophytid.²⁹ In a white woman, aged 55, I have cured a repetitious pompholyx-like eruption of the hands by means of douches of 1:3,000 potassium permanganate and the application of gentian violet to the genitalia, despite the absence of genital symptoms. The "-id" which I refer to, and which is often curable by the use of gentian violet on and within the female genitalia, has been accu-

ately described, but very differently interpreted, by Adamson,³⁰ who considers the essential lesion of eczema, after excluding external causes of dermatitis, as consisting of circumscribed areas of small or large extent, slightly raised, a dull red and studded closely or sparsely with pinhead-sized crusts or with weeping points.

In monilial pruritus of the male or female inguinal or anal regions, and in the disseminated eruptions resulting therefrom, the removal of grease, the daily application of 2 per cent aqueous solution of gentian violet and the superimposition of 1:3,000 permanganate soaks (or sitz baths) will give speedy relief. A single, proper dose of roentgen rays will stop the itching, often within hours; but it will not cure the condition, nor will repetitions of it, for it does not attack the cause, while gentian violet does.

Bland, Rakoff and Pincus³¹ did not report the method of alleviating the monilial infections that they produced in women experimentally. It will be interesting to learn with what means they obtained cures in one week. Hesseltine³² has recently reported an effectual method of treating monilial vulvovaginitis. Plass,³³ he wrote, recommended from 1 to 2 per cent gentian violet applied from three to six times a week; he³² found, however, that iodine is more effective. Taking advantage of the fact that iodine is liberated from a mixture of potassium iodide and potassium iodate in the acid vaginal secretion, he dispenses gelatin capsules of size 00 or 000, each containing 0.125 Gm. of a mixture of 8 moles of potassium iodide to 1 of iodate in sufficient kaolin to fill the capsule. The kaolin must be treated with ammonia before incorporation in order to prevent its acidity from causing premature reaction. Kaolin acts as a diluent preventing vaginal irritation. In addition to ordering two capsules to be placed in the vagina each night, Hesseltine paints the areas with one-fourth strength compound tincture of iodine once a week. He states that he has had cures in a few days or weeks, whether the patient is pregnant or not.

Plass, Hesseltine and Borts³⁴ demonstrated in seven infected women who delivered babies with thrush, the same organism in each mother and child. As Sulzberger,³⁵ Foerster³¹ and others have pointed out, one class of infantile eczema is mycotic. It is, I believe, exceedingly probable that these cases, in which the "eczema" occurs in deep red, circular and oval, circumscribed but coalescing patches of oozing dermatitis, are due to infection with monilia in the birth canal. These differ distinctly from cases due to contact dermatitis (especially wool, silk, oils and soap) and from those classic cases of infantile eczema wherein the cheeks and extensor surfaces of the extremities are the sites of predilection. I have treated patients with infantile mycotic dermatitis with great benefit by the widespread application of the aqueous solution of gentian violet, for it is efficient in moniliasis, nonirritating and nontoxic. I suggest the prevention of such infantile disease by treating asymptomatic monilial vaginitis in pregnant women before parturition by means of gentian violet and permanganate douches, or in any other way that is effectual.

Impetigo or "pemphigus" of the newborn, as Cole and Ruh³⁵ observed in 1914, is a staphylococcal infection, and in its treatment "ointments are worse than useless, serving only to help spread the disease." They recommended astringent agents and dusting powders, a plan of treatment the wisdom of which has been fully borne out by the experience of Swendson and Lee,³⁶ who used silver nitrate and a dusting powder; by that of Carter and Osborn,³⁷ who introduced strong silver nitrate solution into each bulla as it appeared and condemned ointments, and by that of Bowman,³⁸ who used 3 per cent solution of mercurochrome because it is less caustic. Gentian violet solution should here be ideal. It stops autoinoculation in infectious eczematoid dermatitis,³⁹ the identical disease in adults, different only because of the absence of papillae in the dermis of the infant. Gentian violet could easily be used as a bath in the treatment of this condition, and 1:500 dilution would stain the epidermis sufficiently.

Veld sore, as described by Harman⁴⁰ (1904), is in my opinion infectious eczematoid dermatitis, for it starts in a scratch, spreads with herpetoid lesions, is caused by staphylococci and is not benefited by any greasy application. It could be treated effectively with gentian violet.

It is correct to distinguish between staphylococcal and streptococcal bullous dermatitis, I think, as Tachau⁴¹ does. Impetigo, a name properly attached to the streptococcal disease, is characterized by thin walled vesicles; infectious eczematoid dermatitis, the staphylococcal disease, presents thicker walled, more deeply seated lesions which tend to become pustular and which are often associated with follicular and furuncular elements. The early blister in either case contains clear fluid. The treatment is similar, although impetigo generally yields more readily, being more superficial.

Ormsby,⁴² describing the utility of naftalan, permanganate and other drugs in the treatment of yeast and contact dermatoses, has reported gentian violet valuable in the therapy of anogenital and oral thrush, intertrigo and mycotic paronychia.

Gentian violet may be used in ointments. The saturated aqueous solution can be incorporated in any vehicle that will take up water, such as hydrous wool fat. I have found ointment preparations generally unsatisfactory. The dried, greaseless surface after application of the aqueous solution is commonly, as in impetigo, decidedly advantageous. The ointment suffers severely from the objection of messiness, for a dry surface does not stain when touched, but the ointment stains always.

There is, in addition to its mere unsightliness, a contraindication to the use of gentian violet. Case 2 and the accompanying illustration show that it may tattoo the skin with considerable permanence. This observation has not previously been reported, so far as I know.

CASE 2.—Mrs. L. R., aged 79, white, seen Aug. 6, 1937, had a basal cell carcinoma involving the bridge of the nose and the

right lower eyelid. It had first been noticed twenty years previously and had been "burned" several times. I excised it with the pointed cautery with a margin of normal tissue laterally, peeling the skin and thin subcutaneous tissues from the cartilage and nasal bones beneath. The wound was painted with 2 per cent aqueous solution of gentian violet. It was dressed with white petrolatum each day by the patient or by one of her family, and I saw her once a week. By August 27 the burned tissue had sloughed off and granulation was well along, but the edges were thickened, red and tender. I applied gentian violet solution as before. When I saw the lesion September 10 it had healed and consisted of a sound scar but was stained purple, especially at the edge. The color extends into the tissue adjacent to the scar, where, presumably, it was carried by phagocytes after it had been applied to the infected wound. The purple color has faded only a little in eight months.

This case is one of two I have seen in which the application of gentian violet resulted in tattooing. If the dye is applied before the burned tissue sloughs, it is carried away in the sloughing. If it is applied to the granulations, it is liable to tattoo more or less permanently, although this must be quite unusual. It is therefore not advisable to apply gentian violet to ulcerative lesions of the face. This does not include impetigo, the lesions of which are superficial and heal without scar. While I⁴³ have observed tattooing of impetiginized areas resulting from the application of an iron salt, I have not seen tattooing produced by gentian violet in many cases of impetigo contagiosa. Here, too, circumstances must be exceptional when tattooing is to result, but as yet I do not know what they are.⁴⁴

SUMMARY

1. Gentian violet, a mixture of pentamethylpararosaniline chloride and hexamethylpararosaniline chloride, is a medicine of great value in the topical treatment of those external diseases wherein gram-positive bacteria play a part. It is a rich purple dye, available inexpensively in crystalline form, soluble in water, alcohol and chloroform and insoluble in petroleum fractions.

2. Gentian violet is nontoxic and safe to use in local application by swab, soak or bath and on the skin or mucous membranes, and it is notably nonirritating. It has been reported nontoxic in doses of less than 5 mg. per kilogram of body weight when given intravenously to the human being and curative in cases of staphylococcal septicemia.

3. Gentian violet is actively and selectively bacteriocidal or bacteriostatic to gram-positive microorganisms, which include *Staphylococcus aureus*, the gonococcus and diphtheria bacillus; to *Monilia* and, to a less extent, to *Trichophyton*, *Epidermophyton*, *Saccharomyces* and *Torula*. It possesses this property both in vitro and in clinical use.

4. It discolors clothing, skin and linens but can be removed by repeated washings with water and alcohol or can be bleached with chlorine. Its usefulness commonly, although of course not invariably, outweighs the disadvantage of its conspicuous color.

5. Gentian violet in aqueous solution is not irritating; I have not found described nor have I witnessed hypersensitive reactions to its presence on the skin. In alcoholic solution, the alcohol is irritant; alcoholic solutions have very little usefulness on this account. The incorporation of the dye in a salve offers very few

43. Sutton, R. L., Jr.: Pigmentation of the Skin Due to Iron (Copper) Applied Locally, J. A. M. A. 105:112 (Jan. 9) 1937.

44. The possibility that this discoloration might be the result of infection with *B. violaceus*, as observed by Black and Shahan in THE JOURNAL (April 16, 1938, p. 1270), might be entertained. I have not seen what they described; no cultures were made in my case.

advantages and several disadvantages and is commonly, although not invariably, an unsatisfactory method of use. The aqueous solution, 1 or 2 per cent for topical application and from 0.1 to 0.5 per cent for soaks or baths, is the most practicable way to use it.

6. I have found it valuable in the treatment of monilial infections, especially pruritus vulvae and pruritus ani of this origin and the cutaneous eruptions dependent on them; of impetigo, infectious eczematoid dermatitis, infantile furunculosis and secondarily infected eczema, infantile or adult; of Vincent's angina, leg ulcers and ulcers following third degree burns, and of recurrent dermatomycoses, including tinea of the hands and feet. Others have attested its usefulness in foot and mouth disease and vaccinia, as well as in most of those conditions which I quote from my experience.

7. It is urged on the grounds of reason and analogy that gentian violet be tried and assessed in the treatment of pemphigus neonatorum (impetigo, or exfoliative dermatitis of the newborn) and diphtheria of the skin and in the control of pustulation in smallpox and of mycotic infantile eczema.

8. It may be possible to prevent all cases of mycotic infantile eczema that result from infection in the birth canal by the proper antepartum treatment of symptomatic or asymptomatic monilial vulvovaginitis.

9. Gentian violet has been observed to produce tattoo when applied to a deep burn on the face.

THE FEMALE PERINEUM

EPISIOTOMY AND A TECHNIC FOR ITS REPAIR

RAYMOND J. PIERI, M.D.

SYRACUSE, N. Y.

By the term perineum is meant all those structures, or anatomic soft parts, which correspond to the inferior aperture or outlet of the pelvis.

With the marked increase in the percentage of hospital deliveries and in the use of obstetric analgesia during the past decade, surgical incision of these soft parts (episiotomy) during labor has become a common practice by even the most unskilled accoucheurs.

Unfortunately this operation, one of the niceties of obstetric art, is often accomplished with such little regard for either the manner of incision or the technic of repair that the outcome is frequently as undesirable as that which is often observed when no such intervention is attempted. It is not surprising, therefore, that among obstetricians there is a growing sentiment that this is the most abused of obstetric procedures.

On those of us to whom is entrusted the teaching of obstetrics there falls a not altogether undesired criticism for these unfavorable results, since too often our textbooks, our lectures and our clinical demonstrations omit the details of anatomy and technic which the novice requires. The desire for this instruction may be discerned in the multitude of questions concerning the procedure and the structures involved, which, in both classroom and delivery room, are asked by the inexperienced, students, interns and practitioners alike.

Such repeated requests for detailed information have been, more than anything else, the incentive for this presentation.

From the Department of Obstetrics, Syracuse University College of Medicine.

The argument that such operative intervention is not safe in the hands of the average obstetric attendant does not alter the fact that it is the general practitioner who delivers the large majority of expectant mothers. I most heartily subscribe, therefore, to the dictum of my friend and early teacher, Arthur H. Bill,¹ that "we must stop lowering our standards to the level of

Fig. 1.—The female outlet seen from below: AB, the transverse (bisischial) diameter; M, the urogenital triangle; N, the anal triangle; SL, the sacrotuberous ligament.

the untrained man and must begin to think of training men to do the things which we consider ideal."

However, no mere word description of the subject of perineal incision becomes immediately lucid without first a consideration of the chief anatomic features with which the procedure has to deal. First of these is the outlet of the bony pelvis itself (fig. 1).

As originally suggested by Klein,² this may be divided into two triangles (M and N) which have a common base, the bisischial diameter of the outlet (AB) joining the widest parts of the ischial tuberosities. This imagi-

Fig. 2.—Diagram to show the relation of the bony pelvic outlet to the female perineum (seen from below).

nary line traverses the perineum just anterior to the anus.³ The apex of the anterior or urogenital triangle (M) is formed by the subpubic ligament, while its sides are formed by the ischiopubic rami. The poste-

rior or rectal triangle (*N*) is bounded laterally by lines from the extremities of the transverse diameter (*AB*) to the sacrococcygeal joint, which forms the apex. The boundaries of these two figures offer considerable difference, physiologically, in that the anterior triangle possesses for its sides rigid, nonyielding bony barriers, while the sides of the posterior triangle are soft, yielding structures, as the various muscles and fasciae about to be described, and the sacrotuberous ligaments (*SL*).

The various relations between the transverse diameter of the outlet and the triangles just described can better be visualized by figure 2, in which the vulva, perineum and anus, as well as the bony structures, are depicted. Here the importance to the accoucheur of accurate knowledge of the underlying anatomic structures becomes more manifest.

The first step in the study of these structures consists in the removal of the skin and the superficial layer of the superficial fascia (panniculus adiposus), which are identical with the integument and the panniculus found elsewhere in the body (fig. 3). It will now be disclosed that *AB*, the imaginary line denoting the bischial diameter, corresponds rather closely to an ana-

Fig. 3.—Dissection of the female perineum (after Beck). The skin and superficial fascia have been removed. *V*, the vestibule; *CC'*, Colles' fascia covering the urogenital triangle; *CTP*, central tendon of perineum (perineal body); *R*, anus surrounded by external sphincter; *AF*, ischio-rectal fossa; *IF*, inferior fascia of pelvic diaphragm (anal fascia). On the left this has been removed to show *LA*, levator ani muscle; *O*, obturator internus fascia; *AC*, anococcygeal body; *SL*, sacrotuberous ligament; *G*, gluteus maximus muscle.

tomic division between the anterior (urogenital) and the posterior (anal) triangles of the outlet. The anterior triangle is found covered by a fairly dense fascia (Colles' fascia), which is the deep layer of superficial fascia attached laterally to the rami of the pubes and ischia. It is continuous anteriorly and cephalad with the deep layer of the superficial abdominal fascia (Scarpa's fascia) and laterally with the deep superficial fascia of the thigh. Posteriorly, and corresponding generally with the transverse diameter of the outlet, it fuses with the posterior limits of the so-called triangular ligament (urogenital trigon).

In this dissection it will be seen that the anal triangle (*N*) has no such structure as that described as Colles' fascia and that removal of the superficial fat in this region discloses (fig. 3) the external rectal sphincter, the anococcygeal body, the ischio-rectal fossae and the inferior fascia of the pelvic diaphragm (anal fascia), which covers the inferior aspect of the levator muscles. The gluteus fibers usually encountered in this dissection have no obstetric significance.

It is important at this point to become cognizant of the fact that in both their anatomic features and their function the anterior (urogenital) triangle differs markedly from the posterior (anal). Careful dissection of the anterior triangle discloses that it is composed of various perineal compartments arranged in layers (fig. 4), the most superficial (inferior) of which is opened

Fig. 4.—Dissection of the anterior (urogenital) triangle: *C*, Colles' fascia reflected to show the muscles of the left superficial perineal compartment; *BC*, bulbocavernosus; *IC*, ischio-cavernosus; *PS*, superficial transverse perineal; *T*, inferior fascia (floor) of deep compartment (urogenital diaphragm, urogenital trigon, or triangular ligament).

by reflecting Colles' fascia laterally. This exposes to view the ischio-cavernosus, bulbocavernosus (constrictor cunni) and the superficial transverse perineal muscles.

The former arises on the mesial surface of the ischial ramus, passes anteriorly and medially and becomes inserted on its own side into the fascia of the inferior surface of the clitoris.

The bulbocavernosus (constrictor cunni, or sphincter vaginae) arises in the central tendon of the perineum (*CTP*), passes anteriorly, lateral to the vagina, and is inserted into the fibrous sheath of the clitoris.

Fig. 5.—Further dissection of the urogenital triangle: *CC'*, Colles' fascia has been reflected and the contents of the superficial compartment removed. On the left *T*, the inferior fascia of the urogenital diaphragm has been reflected to show the muscles of the deep perineal compartment. *MP*, sphincter muscle of the membranous urethra. *PP*, deep transverse perineal muscle. *T'*, superior fascia (roof) of urogenital diaphragm. In the posterior (anal) triangle the obturator fascia (*O*) has been removed on the left, showing the underlying fibers (*O'*) of the obturator internus.

The superficial transverse perineal muscle takes origin from the ischial tuberosity and extends medially across the superficial perineal compartment or space to its insertion into the central tendon of the perineum.

The roof of the compartment thus dissected can be discerned (fig. 4 *T*) as the inferior of two layers of a thin fascia which enclose the so-called deep perineal compartment (the urogenital diaphragm, triangular ligament or urogenital trigon).

Deeper dissection, with reflection of all the structures of the superficial compartment and the inferior layer of fascia (floor) of the urogenital diaphragm (fig. 5), reveals the contents of the deep compartment.

Fig. 6.—The levatores ani (pelvic diaphragm) seen from below. The inferior (anal) fascia has been removed. PC, pubococcygeus fibers; L, ileococcygeal portion; CG, coccygeus muscle; W, the "white line."

Arising from the ischial ramus laterally and extending medially across the deep perineal interspace, the deep transverse perineal muscle (*PP*) becomes inserted into the central portion of the perineal body.

From the ischiopubic ramus the sphincter muscle of the membranous urethra (*MP*) passes anteromedially to join its fellow of the opposite side, some fibers surrounding the urethra while others are attached to the lateral walls of the vagina.

The roof of the deep perineal compartment (*T'*), as previously indicated, is the superior fascia of the triangular ligament. This "ligament," or diaphragm, is the

Fig. 7.—Right mediolateral episiotomy.

continuation of the obturator fascia which crosses the anterior triangle of the pelvic outlet. Laterally its two layers are attached to the ischiopubic rami. Posteriorly, and roughly coinciding with the bischial line, they fuse with each other and with Colles' fascia. In the midline the various compartments described (figs. 3, 4 and 5) are perforated by the urethra and vagina.

The ischiorectal fossae (*IF*) extend anteriorly from the posterior (anal) triangle between the superior fascia of the urogenital diaphragm and the inferior levator (anal) fascia. Thus the superior fascia of the urogenital trigon forms also the floor of the anterior extensions of the ischiorectal fossae, while the roof is formed by the anal fascia (inferior layer of the pelvic fascia).

At this point it might be well to describe briefly the various planes of the pelvic fascia. The anal fascia covering the inferior surface of the levator ani is the inferior of two layers of fascia (the pelvic fascia). The upper layer covers the superior surface of the pelvic diaphragm (levator ani). Laterally on each side, and corresponding closely to the origin of the levator muscle, both layers of this pelvic or diaphragmatic fascia fuse with the fascia which covers the inner surface of the obturator internus. The ridge so formed is called the arcus tendineus of the levator ani, or the "white line." Shortly below (medial to) this line the layer of fascia on top of the levator ani (superior layer of levator fascia) thickens to form a bandlike base or

Fig. 8.—First layer of sutures. (The placenta has been delivered.) The first stitch (submucous) is passed widely around the upper angle (*aa'*).

ridge of fascia, the tela endopelvina,⁴ or main sheet of visceral fascia,⁵ which gives off four layers, one going to the bladder, a second between the bladder and the vagina, a third between the vagina and the rectum and the fourth posterior to the rectum. The proper support of the pelvic viscera depends on the integrity of these fascial layers as well as on the integrity of the muscles.

Removal of the various structures which comprise the urogenital trigon and of the inferior levator (anal) fascia discloses (fig. 6) the arrangement of the fibers of this most important paired muscle, the pelvic diaphragm. For purposes of description as well as anatomically two parts of each levator are visualized. The first portion (pubococcygeus) arises slightly external to the symphysis and from 3 to 4 cm. below the pelvic brim. These fibers (fig. 6 *PC*) pass directly backward, lateral to the vagina, some decussating in the perineal body (a point disputed by some), others mingling with the longitudinal fibers of the vaginal wall, still others

Obst. & Gynec.* 25: 484-492 (April) 1933; *Further Studies of Fascial Planes Surrounding Vagina*, *ibid.* 26: 614-620 (Oct.) 1933; *Pelvic Fascia; Histologic Structure of Planes of Tissue Used in "Fascia Overlapping" Operation to Correlate Conflicting Views*, *ibid.* 29: 834-839 (June) 1935.

ending in intimate relation with the fibers of the external sphincter, while the remainder join with those of the opposite side posterior to the rectum (anococcygeal body) prior to their insertion in the coccyx.

The second (lateral) portion of the levator (ileococcygeal portion) may be seen arising from the "white line" of the tendinous arch, which extends downward and backward to the ischial spine, where it is about 5 cm. below the plane of the inlet. The greater portion of these fasciculi pass downward and backward, some joining fibers from the opposite side, others becoming inserted in the anococcygeal body (fig. 6 AC) and the remainder into the lateral margins of the coccyx. Posterior to the levator closure of the aperture of the outlet is completed by the coccygeus and to some extent the piriformis muscle, neither of which is of great obstetric significance.

Thus the conformation of the pelvic floor assumes somewhat the shape of a trough, closed behind (anococcygeal body) and open in front (vagina). The function of this V shaped arrangement of structures, aside from its mechanism in giving support to various viscera, becomes manifest during childbirth, as it guides the

Fig. 9.—First layer of sutures tied and cut.

presenting part along the path of least resistance by way of the vagina through the pelvic outlet and into the outside world.

That portion of the perineum which lies between the vagina and the anus is termed the perineal body (fig. 3 CTP). It is composed, as earlier disclosed, of the various perineal muscles, which are joined at this point, and of their various fascial investments. During pregnancy, through vascular and other changes, the perineal body as well as the entire floor of the perineum projects from 2 to 4 cm. below the customary level of the non-pregnant state.

As a result of excessive strain during labor, overstretching or laceration of the muscles of the perineum frequently occurs. This is invariably accompanied by single or multiple tears in one or more of the various layers of pelvic fascia, which in many places is in such intimate relation to the perineum as to be considered a part of it. These injuries, by weakening the support of the pelvic organs, constitute one of the chief factors in the production of such sequelae as cystocele and rectocele.

By episiotomy is meant the operation whereby the perineum is incised during delivery to prevent laceration of the soft parts at the pelvic outlet. It merely substitutes "a clean cut of definite size in a place where

it can do the least harm for a ragged tear of indefinite size in a place where it may cause immediate danger and subsequent injury."⁶ Strictly speaking, any such incision of the perineum may be termed episiotomy, whether lateral or bilateral, mediolateral or central. The lateral incisions have fallen more or less into disfavor. By popular usage the term episiotomy has

Fig. 10.—The second layer of sutures includes the deep superficial fascia. The "crown" stitch (buried) includes the bulbocavernosus fibers.

come to signify an incision of the vulvar ring directed away from the sphincter ani (mediolateral episiotomy), to distinguish it from "perineotomy," or central episiotomy, an incision along the central raphe and directed toward the sphincter.

As an obstetric procedure it is nothing new, since it is recorded that the vulva was incised by Ould in 1742. In the years that followed, Michaelis (1810), and subsequently Ritgen, Schultz, Scanzoni, Colpe and Credé, in as many variations of technic as there were

Fig. 11.—Subcuticular interrupted sutures close the skin.

accoucheurs, made one or several incisions to secure the additional space needed for delivery. It is not clear whether these outstanding early protagonists repaired their incisions or left them to nature. Anesthesia during childbirth was not then the vogue.

After 1918, when Pomeroy⁷ presented a paper on the subject, episiotomy gained increasing favor among the profession, particularly after many other leading

6. Cameron, J. C.: *An American Text-Book of Obstetrics*, Philadelphia, W. B. Saunders Company, 1895.

7. Pomeroy, R. H.: Shall We Cut and Reconstruct the Perineum for Every Primipara? *Am. J. Obst.* 78: 211-220 (Aug.) 1918.

authorities, notably De Lee,⁸ emphasized the advantages of the operation both to the baby and to the mother. The indications and contraindications have been enumerated by Schauta,⁹ Anspach,¹⁰ Berlind,¹¹ Galloway,¹² Taylor¹³ and others and are beyond the scope of this paper. However, expressed in a few words, the advantages to the baby lie chiefly in the shortened period of

Fig. 12.—Allis clamps are used to seal the edges of the incision.

pounding of the fetal head on the perineum and the consequent reduction in the incidence of cerebral injury. As for the mother, the second stage is shortened, while the restoration of the pelvic floor after episiotomy properly performed is usually better than is observed even after many normal deliveries in which no visible lacerations occur, the integrity of the soft parts remaining often as unimpaired as in their nulliparous state.

The technic of the incision is simple. In the absence of any indication for earlier intervention delivery is not attempted until the presenting part is on the levators and there is evidence of pressure on the vulvar outlet. This is recognized both by some bulging of the perineum and by a beginning distortion of the anus.

After the usual preparation for delivery the bladder is catheterized and the perineum gently "ironed out" with the liberal use of neutral liquid soap. Care should be exercised here to avoid overstretching of the parts and too rapid dilation. The former causes future loss of muscle tone and damage to the fascia, while the latter favors laceration.

The site of incision depends on the operator, the right or left mediolateral episiotomy being favored by most accoucheurs chiefly because it avoids the rectum. The point of direction extends from the midpoint of the posterior aspect of the vaginal orifice and proceeds along a line midway between the sphincter and the ischial tuberosity (fig. 7). This is best accomplished by means of sharp scissors, the angle of the blades being placed at the middle point of the fourchette, the inner blade inserted between the presenting part and the parts to be incised. The external blade demarcates

the direction and extent of the incision, which is usually accomplished by a single quick motion. Grasping the parts between the thumb and forefinger facilitates an accurate incision. With the operator seated during delivery, as is the custom with me, the right-sided incision is the most easily accomplished. The particular structures severed by the episiotomy depends on the length of the incision. At times, as recommended by Dührssen in pathologic cases, even the ischioanal fossae are involved. Ordinarily, however, one severs the skin, Colles' fascia, the bulbocavernosus, the transversus perinei, the urogenital septum and the median fibers of the pubococcygeus portion of the levator ani.

Following delivery, which usually shortly succeeds the episiotomy, bleeding ceases. If persistent, hemorrhage is easily checked by means of a firm tampon until sutures are applied. Delivery of the placenta is to be preferred before the repair is begun in order that a vaginal sponge, inserted high in the birth canal, may assist in keeping the field clear and because the placenta, by its bulky size, may cause damage if delivered after suturing is completed. Any suitable retractor may be used for exposure if desired.

Ordinarily on inspection of the incision the details of individual anatomic structures are not recognized, except for muscle tissue and Colles' fascia, which is usually found retracted under the integument and superficial panniculus. More accurate identification of layers is unnecessary.

The technic of repair about to be described has seemed to me to offer certain advantages over other methods which I have employed in that it follows certain established surgical principles¹⁴ and causes a minimum amount of postoperative discomfort. All sutures are of fine texture, my opinion coinciding with that of Harvey¹⁵ that it is never necessary to use any suture stronger than the tissue through which it passes.

Fig. 13.—Removal of the Allis clamps leaves a fine linear scar.

Single sutures are preferred to double sutures, since the difference in their holding strength is practically negligible.

The first layer of sutures, therefore, is interrupted (chromic No. 1), passed widely to reduce tension on the line of healing and tied just securely enough to secure coaptation. Care is observed, of course, to avoid perforation of the rectum. The first stitch (fig. 8 aa') is submucous and is passed in circular fashion around

the upper angle of the incision. This brings together any fibers of muscle or fascia which might have separated under the mucosa. Neglect in this detail favors subsequent "pouching" of the posterior vaginal wall, or even a later rectocele, if such an occult separation exists.

The second layer of sutures (fig. 10) includes the fascia of Colles. No. 0 chromic gut is selected here because of its ample holding strength (8 pounds) in fascia.¹⁶ It is at this time that the "crown" stitch is inserted, bringing together the severed portions of the hymen, the needle being inserted obliquely upward in the base of the labia minora to secure in its grasp the retracted fibers of the severed constrictor cunni (bulbo-cavernosus) muscle. To overcome this retraction and to prevent gaping of the vagina, two such sutures may be required. To avoid "dead space" any muscle underlying the fascia is included in the bite of the needle as it is passed from one side to the other.

When completed the second layer usually brings into apposition the edges of both the mucosa and the skin respectively. Frequently, however, to insure this a third (subcuticular) layer of 00 or 000 catgut (fig. 11) is placed, a fine skin needle being used. No sutures are passed through either vaginal mucosa or skin, those portals of entry which invite pathogenic organisms from without to follow the suture into the tissues below thus being eliminated.

As a final step the line of incision is effectively sealed by gentle coaptation of its everted edges by means of Allis clamps (fig. 12). A dozen of these instruments are ready for use in each case. These are applied and permitted to remain clamped for only a few moments while the vaginal pack is removed, any blood clots are expressed and preparations are completed for the transfer of the patient to her bed. Removal of the clamps leaves a fine linear scar, which for a brief interval remains elevated as the result of the eversion and then becomes almost imperceptible as the elevation recedes. It is surprising how apposition of the cut edges of the wound in this manner makes adherence quite effective and renders unnecessary even the use of skin clips, as recommended by Mathieu,¹⁷ the objection to clips being their discomfort and the necessity of their removal several days later.

In the early cases in which repair was done in the manner described there was occasionally encountered a repair in which a small area of separation of the edges of the skin developed at the lower angle. This was overcome by passing the subcuticular suture at this point widely around the angle (fig. 11).

While inferences are not always accurate, the results of repairs following this technic have been gratifying. There has seemed to be much less discomfort to the patient, and no case of infection or "breaking down" of the perineum has been observed in the present series of more than 400 cases.

SUMMARY AND CONCLUSIONS

1. There has been a great increase in the frequency of the operation of episiotomy by the general practitioner.
2. Owing in a large measure to inadequate instruction of physicians, the end results of many such operations are disappointing.

THE NEED OF REDETERMINING SCHICK NEGATIVENESS IN SCHOOL CHILDREN

A. B. SCHWARTZ, M.D.

AND

F. R. JANNEY, M.D.

MILWAUKEE

Diphtheria morbidity and mortality in the United States has been enviably low in the past ten years.¹ Furthermore, there has been, as pointed out by Jordan,² a naturally declining trend in diphtheria since 1895. The low incidence of clinical diphtheria makes it all the more important to maintain the Schick immunity of the large school population, since it has been shown by Dudley³ and others that the duration of the immunity depends a great deal on natural restimulation of the immune response by exposure to diphtheria environment. In the comparatively diphtheria free environment of American cities this restimulation of the immune response is absent, and therefore one might expect a relapse of immunity to occur more frequently.

During the years 1929 and 1930 we⁴ reported the successful use of toxoid as an immunizing agent in the preschool child. In a recent retesting of 145 of those children who had received toxoid and had shown a negative Schick test six or seven years previously, 22 per cent showed a reversion to a positive Schick test. Fraser and Halpern⁵ at the University of Toronto have recently called attention to a similar occurrence. One third of the children retested by them had lost their immunity within five years.

The recent report of Park⁶ suggests that a large number of reversions to a positive Schick test may be expected following one dose alum toxoid.

During the last year or two there has been an apparent increase in the incidence of diphtheria among supposedly Schick negative children. These occurrences warrant serious consideration of the present status of Schick immunity in our large school population.

As it is now the practice to immunize against diphtheria at about 9 months of age and to perform a Schick test within the following several months, many school children have had an interval of five years or more following the immunization procedure by the time they enter school.

The importance of a Schick test following the immunization procedure has been repeatedly empha-

sized. By means of the Schick test, varying degrees of effectiveness have been recorded for different materials; but, once a negative Schick test has been obtained, the immunity has been generally assumed to be permanent.

Whatever materials or method of immunization is followed, the immunity of the school child to diphtheria should be insured by either a routine Schick testing on all children entering school or by the administration of a routine dose of 1 cc. of toxoid at the time of entering school, as suggested by Fraser and Brandon.⁷

In order to maintain the low incidence of diphtheria in the United States, one of these two measures should be made a routine part of our preventive medicine program.

Clinical Notes, Suggestions and New Instruments

RHEUMATIC FEVER FOLLOWED BY MITRAL HEART DISEASE IN EACH OF IDENTICAL TWINS

J. E. MORGAN, M.D., AND S. J. WEBSTER, M.D., CLEVELAND

For many years the occurrence of simultaneous pathologic processes in homologous twins has aroused the curiosity of medical men. Recently it has been realized what interesting side lights such cases throw on both the etiology of disease and on genetics. Reports of such cases have been numerous in the literature. Many pairs of homologous twins have been born with identical developmental defects.¹ Others have almost simultaneously had various neoplastic diseases in middle or late life. Still others have had certain metabolic diseases, such as diabetes, within a few months of each other.² Other twins have had identical psychic disturbances varying from actual psychoses to similar alcoholic propensities.

It has been our privilege to observe mitral heart disease, following rheumatic fever, in each of identical twin girls. Since the case brings out some interesting points and since a survey of recent literature showed no similar case, we felt that it should be reported.

REPORT OF CASE

Annie F., a Slavish-American girl, aged 23, first consulted us Feb. 27, 1937. Her story was briefly as follows:

Six weeks before, her twin sister had died of "heart trouble." Ever since the death of her sister, the patient had feared that her heart also was affected. She had noticed precordial oppression, palpitation, and shortness of breath on slight exertion. These, she stated, were exactly the same symptoms which her sister had first noticed. The patient felt that her symptoms were probably due to an overwrought imagination, but she had decided to consult a doctor to still her fears. Feeling that she was highly distraught and that her symptoms were probably functional, we proceeded to examine her. She was rather slight and undernourished, evidently not in robust health. Surprisingly, examination of her heart, both by physical means and by the fluoroscope, did show typical signs of a far advanced rheumatic heart disease with well developed mitral stenosis.

Further delving into her history then brought out the following facts:

The twin girls, Annie and Mary F., were born Jan. 28, 1914. They were full term, healthy babies, and each is reported as weighing 7 pounds (3,175 Gm.). It was the mother's second pregnancy. Her first child died at 3 years of age of pneumonia. She had six subsequent pregnancies. All these children are alive and healthy. There were no other multiple pregnancies and, moreover, none were known on either side of the family.

The twins, as babies, were quite healthy and developed normally. The mother said that they were "always like as one"; that they were the same height and weight; that they talked alike and apparently even thought alike, as their reactions to a given situation were very similar. She stated that she could tell the girls apart from a front view but not from the back.

As is not surprising, the contagious diseases of childhood, measles, whooping cough and chickenpox, occurred simultaneously or nearly so.

At 15 years of age, Mary first acquired a cold and then multiarticular rheumatism, which began in her feet and ankles and migrated to her hands, wrists, elbows, shoulders and knees. The joints were swollen, red and acutely painful. She had a high fever and was quite ill. The attending physician made a diagnosis of rheumatic fever and told the mother at that time that the child's heart was affected.

Two weeks after the onset of Mary's illness, Annie developed the same train of symptoms. Her disease began in the same manner, starting in the feet and spreading to the other joints. The course was milder and she was not as ill as her sister at any time. The two girls remained in bed at home and recovered at the same time, getting up in about six weeks. The attending physician did not state whether or not Annie showed cardiac involvement. None of the other children were affected.

After recovering from this acute attack, both girls seemed well. They were active and were able to assist with the work of the home without discomfort. They never took part in gymnasium work at school because of the advice of their doctor.

About three years after the acute attack, Mary began to have marked shortness of breath on exertion. The attending doctor told the parents that she had rheumatic heart disease and advised rest and medication. The disease became progressively more and more severe and she died Jan. 13, 1937, of congestive heart failure.

In summary, two sisters, evidently identical twins, had rheumatic fever within two weeks of each other at 15 years of age. At 18 Mary began to show symptoms of congestive heart failure due to rheumatic heart disease. She died at 23, eight years after the primary attack of rheumatism. Now, just after the death of her sister, Annie shows signs of well developed mitral stenosis and is apparently on the verge of decompensation.

Dr. J. F. Machwart, who attended these girls during their early illness, has assured us that their first attack was typical rheumatic fever and that Mary had typical mitral stenosis before her death.

COMMENT

In such a case as the one presented, it is interesting to speculate why acute rheumatic fever should appear simultaneously in homologous twins and follow such a similar course in its progress to far advanced mitral heart disease. Identical twins probably develop from the two halves of a single fertilized ovum. They therefore should contain, as nearly as the vicissitudes of mitosis permit, exactly similar amounts of chromosome material. Therefore their hereditary potentialities of development, both anatomic and psychic, should be identical. The occurrence of similar developmental defects in each of homologous twins certainly suggests that the anlage of the malformation was present in the genes of the original fertilized ovum. Similar simultaneous and symmetrical development of neoplasms in homologous twins speaks for a definitely hereditary origin in the sense that the tumor must have had an original representation in the genes of the germ cell. Similarly, because of their occurrence in identical twins, it has been argued that the potentiality for developing certain metabolic diseases is a definite hereditary character and can be transmitted in a true mendelian ratio. None of these explanations, of course, fit our case. Rheumatic fever, while still not of proved etiology, is probably an infectious disease. It does not, however, have a high degree of infectiousness. It is definitely unusual for two children in the same family to be stricken with the disease at the same time, and that its course should be so similar certainly seems to suggest that there is a hereditary constitutional susceptibility which determines when

even the infectious diseases shall be developed and guides their course along a predetermined path. This would be in agreement with Draper,³ who defines constitution as "that aggregate of hereditary characters, influenced more or less by environment, which determines the individual's reaction, successful or unsuccessful, to the stress of environment."

Although it is not apropos to the case being reported, we have recently made another interesting observation. In his excellent review of the diseases occurring in twins, McFarland¹ feels that the following generalization is justified: "Heterologous twins never suffer from identical malformations. Nor does one of homologous twins ever suffer from malformation not shared by its fellow." About six months ago we delivered a pair of heterologous twins, male and female, both of whom had bilateral clubbed feet. The clubbing of the two pairs of feet was identical in type, but the feet of the girl were less severely deformed and yielded to treatment more readily than those of the boy. It is difficult to explain such a case. It is hard to see how position in utero could account for similar and symmetrical clubbing of the two pairs of feet. Heterologous twins should have nothing more in common, from the strict point of view of heredity, than any other brother or sister from the same parents. Therefore if the malformations are on a strictly hereditary basis, they must have been an extremely rare coincidence. Other cases of similar malformations occurring in heterologous twins should be watched for, as they might throw light on this intriguing subject.

No attempt has been made to cover the theories of twinning or the laws of heredity covering this subject. For these, as well as for a complete bibliography, reference may be made to the large reviews of the subject.

CONCLUSIONS

A case of acute rheumatic fever developing to mitral heart disease in each of homologous twins would seem to present supportive evidence of a hereditary constitutional susceptibility to certain of the infectious diseases.

A case of similar malformation occurring in each of heterologous twins was observed.

PROLONGED USE OF "MERCURIN" SUPPOSITORIES IN THE TREATMENT OF CHRONIC EDEMA

J. L. CAUGHEY JR., M.D., NEW YORK

The use of rectal suppositories for the administration of mercurial diuretics has been recognized as a simple and effective method of treating chronic edema of nonrenal origin.¹ There has been some doubt as to the advisability of this type of treatment, because of the possibility of severe local irritation.

Without giving details, Christian states that "this treatment may be kept up for months with no bad effects." Fulton noted no unfavorable reaction after the administration of fifteen "Mercurin" suppositories to a single patient.

Two cases are reported here. In each one "Mercurin" suppositories² were used for more than a year with good diuretic effect and no evidence of rectal irritation.

REPORT OF CASES

CASE 1.—A. L., an Italian-born white housewife, aged 35 on admission, had pleurisy and ascites when she was 11 years old, followed by dyspnea on exertion and chronic but variable swelling of the legs and abdomen. When admitted to the Presbyterian Hospital in 1932, physical examination showed a heart of normal size with normal heart sounds, a right-sided hydrothorax, an enlarged liver and spleen, ascites, and edema of the legs up to the thighs.

3. Draper, George: Human Constitution, Philadelphia, W. B. Saunders Company, 1924.

¹ From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

1. Christian, H. A.: New England J. Med. 214: 418 (Feb. 27) 1936; Fulton, M. N.: ibid. 214: 1092 (May 28) 1936. Parkinson, John, and Thomson, W. A. R.: Lancet 1: 16 (Jan. 4) 1936. Thomson, W. A. R.: Quart. J. Med. 6: 321 (July) 1937.

2. The "Mercurin" suppositories used were provided by Campbell Products, Inc., of New York.

Laboratory examinations gave the following results: Hemoglobin was 62 per cent (Sahli); red blood corpuscles numbered 3,940,000 per cubic millimeter. The white blood cell count was normal. The urine was normal. The Wassermann reaction of the blood was negative. Serum protein was 4 per cent. The pleural fluid was a pale straw color; specific gravity was 1.010; cells were 210 per cubic millimeter, lymphocytes 96 per cent; a guinea pig injected with the fluid showed no tuberculosis at autopsy. The T waves in an electrocardiogram under low voltage were isoelectric in all leads.

The diagnosis was probable constrictive pericarditis (Pick's syndrome).

There was no progression of the symptoms until 1935, when weakness, dyspnea and swelling of the abdomen and legs became more pronounced. Study at that time showed hemoglobin 60 per cent, red blood corpuscles 5,600,000 per cubic millimeter, serum protein 5.2 per cent, serum albumin 3.2 per cent, serum globulin 2 per cent and venous pressure 150 mm. of water (direct method).

Following transfusion and large doses of iron the anemia disappeared and she felt much improved, though enlargement of the liver and dependent edema persisted. The possibility of pericardial surgery was discussed, but the patient declined to have such an operation.

In July 1936, because of some increase in ascites and dependent edema, she started treatment with mercurial diuretics, administered intravenously or by rectal suppository. In the subsequent seventeen months she had sixteen injections of "Mercurin"³ intravenously and fifty-five "Mercurin" suppositories.

She has been ambulatory on limited activity throughout this time. There has been symptomatic improvement, lasting several days, after each use of the mercurial diuretics. She has had no symptoms of rectal irritation, but she does have mild abdominal cramps after each dose of mercury, whether given intravenously or by rectum.

CASE 2.—R. C., a native-born Negress, aged 42 on admission, had acute rheumatic fever for two months at 24 years of age and was told that her heart was damaged. In spite of an active and strenuous life and four pregnancies, she had no cardiac symptoms. In October 1933, at the age of 39, she had a supravaginal hysterectomy because of pain and excessive bleeding from uterine fibromyomas. The heart was described as normal and the postoperative recovery was uneventful.

Two months after this operation she began to have precordial pain, dyspnea on exertion and swelling of the abdomen and legs. She was admitted to the Presbyterian Hospital in June 1935 because of steady progression of these symptoms. Physical examination revealed an enlarged heart, with a systolic murmur and a transitory pericardial friction rub at the apex, passive congestion of the lungs, small right-sided hydrothorax, liver enlarged to 4 cm. below the costal margin, moderate ascites and pitting edema of the legs and over the sacrum.

Laboratory examinations gave the following results: Hemoglobin was 80 per cent (Sahli); red blood corpuscles numbered 3,950,000, the white blood cell count was normal and the urine was normal. Serum protein was 5.5 per cent and serum nonprotein nitrogen 24 mg. per hundred cubic centimeters. The Wassermann reaction of the blood was negative. A teleroentgenogram of the heart revealed the total diameter to be 17 cm.; the internal diameter of the chest was 26 cm. In an electrocardiogram under low voltage, the T waves were inverted in all leads. The venous pressure was 240 mm. of water.

The diagnosis was active rheumatic myocarditis, possible constrictive pericarditis or disorder of the tricuspid valve.

The patient refused to consider a pericardial operation and she was not urged to do so because the large size of the heart revealed by x-ray examination seemed to make the diagnosis of constrictive pericarditis doubtful. Because of persistent ascites an abdominal paracentesis was done in December 1935 with the withdrawal of 6,000 cc. of clear fluid, which coagulated quickly. A guinea pig injected with this fluid showed no tuberculosis at autopsy.

Dyspnea, edema of the legs and ascites continued to be present in variable degree even though the patient's activity was greatly limited. In October 1936, because of increasing symptoms, the

3. Now called "Mercurin with Theophyllin."

administration of mercurial diuretics was begun. In the next thirteen months she received eighteen injections of "Mercurpurine" intravenously and thirty-five "Mercurin" suppositories. At no time did she have any symptoms of rectal irritation.

Her course was satisfactory until September 1937, when she discontinued her medication temporarily and had a great increase in the severity of her symptoms. Results obtained from further medication were not good, and she died in November.

Permission for postmortem examination was limited to the heart. The pericardial sac was large, but its surface was smooth and there were no adhesions to the wall of the chest or the pleura. The parietal pericardium was very thick, varying from 3 to 8 mm. in cross section, and was of a leathery consistency. The pericardial cavity was partially obliterated but contained more than 80 cc. of serosanguineous fluid. The heart itself was not enlarged. The mitral valve leaflets were thickened, but there was no stenosis of the valve. Microscopic examination revealed no evidence of active myocarditis or endocarditis, and the thick pericardium showed no evidence of any recent inflammatory process.

SUMMARY

Prolonged administration of mercurial diuretics by rectal suppository ("Mercurin") was given to two patients with no rectal disorder. Fifty-five were given to one patient and thirty-five to the other, without symptoms of rectal irritation.

622 West 168th Street.

THROMBO-ANGIITIS OBLITERANS IN SISTERS

NATHAN D. WILENSKY, M.D., AND WILLIAM S. COLLENS, M.D.
BROOKLYN

The rarity of thrombo-angiitis obliterans in women is revealed by the fact that a total of twenty-two case reports have appeared in the literature. We have recently had a very unusual experience in observing this disease in two sisters. To our knowledge this is the first observation of its kind. We are thus prompted to present the clinical histories.

REPORT OF CASES

CASE 1.—P. L., a Polish Jewess, aged 34, who came under observation on Sept. 4, 1937, had noticed five years before that walking produced an aching pain and cramps in her feet and legs. Her claudication became progressively worse, so that at the time of examination she was unable to walk more than one-half block. The pain was relieved only after a few minutes of rest. She also complained of cold feet and noticed their pale appearance. She had formerly been employed as an artificial flower worker but was compelled to give up her occupation because she experienced severe pain in the muscles of her left hand and arm during work. For the last six months she had had two painful ulcers, the size of a quarter (24 mm.), on the lower third of her right leg, and they had failed to heal in spite of a wide variety of therapeutic attempts. Former treatments consisted of intravenous injection of typhoid vaccine three times a week for four weeks, eight intravenous injections of hypertonic saline solution, suction and pressure treatments, diathermy and local application of ointments.

The patient had smoked three cigarets a day up to four years ago, when she was told to stop smoking because of her circulatory disturbance. She had not been observing any dietary restrictions, and rye bread was part of her regular intake.

Physical examination revealed that she was well nourished and well developed. The blood pressure was 120 systolic and 90 diastolic. She weighed 135 pounds (61 Kg.) and was 62 inches (157 cm.) tall.

Examination of her extremities showed a slight pallor of both feet in the recumbent position. They became cadaverous on elevation, and in the dependent position a marked cyanotic rubor developed. Both feet and legs were cold to the touch. The venous filling time was sixty seconds for both legs. Pal-

pable pulsations were absent from both dorsalis pedis, posterior tibial and popliteal arteries. The left radial and ulnar vessels were not palpable. The left hand was cold to the touch. The vessels of the right hand were palpable and the extremity was warm. The oscillometric readings are shown in table 1.

Cordlike veins were felt in both legs. The Wassermann reaction of the blood was negative. The blood count was

TABLE 1.—First Oscillometric Readings in Case 1

Dorsalis pedis	0	0

normal and urinalysis gave entirely negative results. The blood sugar content was 94 mg. per hundred cubic centimeters. X-ray examination of both legs and the left arm showed no signs of calcification. Examination of the eyegrounds gave negative results.

We have had an opportunity to observe two attacks of migrating phlebitis in the patient's left leg since she came under our care.

She was put to bed under a cradle baker with the heat maintained at 95 F. and was given intermittent venous occlusion at 30 mm. of pressure, starting with one minute on and two minutes off, continuously. She was also given twenty minutes of short wave treatment three times a week. Azochloramid ointment was applied locally to the ulcers, and the pain was relieved in three days. After one week of treatment the intermittent venous occlusion was reduced to eight hours a day. There was marked improvement in her walking ability, as indicated by the claudication time test. Although she could formerly walk only one-half block, she was now able to walk two and one-half blocks before experiencing a cramp. On October 18 the ulcers had completely closed over. Dr. Charles Goodman performed intradermal tests for rickettsia and found them positive with various dilutions. At the present time her feet are warm and sweaty. She has no pains when at rest. Her venous filling time is thirty seconds in her right foot and thirty-five seconds in her left foot. The cadaverous color has disappeared. Her oscillometric readings taken six weeks after the institution of treatment are shown in table 2.

CASE 2.—Mrs. S. M., aged 40, a sister of Mrs. P. L., has had intermittent claudication for the past fourteen years. It was originally present in the muscles of the right foot and has

TABLE 3.—Oscillometric Readings in Case 2

	Lower Extremities	
	Right	Left
Mid thigh	3 ½	3
Below knee.....	3	2
At ankle.....	½	½
Dorsalis pedis....	¼	0

recently progressed to the muscles of the calf. For the past four years she has had numbness and coldness in the toes of the left foot. At present she has pain when at rest and burning pain and a sensation of pins and needles in all of her toes. Unlike her sister, she has no history of migrating phlebitis.

She had typhus fever as a child. She has never smoked, she uses rye bread in her diet and she does not consume any alcoholic drinks. She is married and has two normal sons.

Physical examination revealed that she was well nourished and well developed. The blood pressure was 130 systolic and 90 diastolic. She weighed 126 pounds (57 Kg.), and she was 60 inches (152 cm.) tall. Her heart was normal. Examination of the eyegrounds did not show any vascular changes. Examination of the urine gave entirely negative results.

All of her toes had a cadaverous appearance. The arterial pulsation of the dorsalis pedis was felt in the right foot and was absent in the left foot. When she elevated her legs the plantar surfaces became blanched, the left more than the right, and she complained of an aching cramp in the toes of her left foot. The venous filling time was fifteen seconds in the right and twenty-five seconds in the left foot. X-ray examination failed to disclose any evidence of calcification of the arteries of the legs and the feet. However, a phlebolith was seen in one of the veins of the calf. The intradermal test for rickettsia was markedly positive with all dilutions. Oscillometric readings for both legs are shown in table 3.

These signs clearly indicated evidence of arterial impairment of thrombo-angiitis obliterans.

COMMENT

It would appear that these two cases present sufficient clinical evidence and all the criteria necessary to establish the diagnosis of thrombo-angiitis obliterans. There was a history of progressive intermittent claudication, coldness and paresthesias of the feet and toes, impairment in circulation as indicated by reduced oscillometric readings, absence of palpable pulsations, prolongation of the venous filling time, confirmatory plethysmographic studies and failure of ulcers to heal. The pathognomonic sign of migrating phlebitis was present in one case. The absence of calcification, the normal blood pressure, the negative serologic tests and the absence of any evidence of diabetes tend to rule out other possible causes of the occlusive arterial disease.

Smoking apparently had little to do with the onset or progress of the disease in either of these cases. One patient had smoked only moderately up to the time of onset of her symptoms, and the disease progressed in spite of cessation of this habit. The sister had never smoked at all.

1908 Avenue K—123 Eighth Avenue.

HAND INJURIES DUE TO INJECTION OF OIL AT HIGH PRESSURES

DONALD E. DIAL, M.D., CLEVELAND

Rees¹ has called attention to the absence of reports of injuries resulting from the injection into the tissues of oil under high pressure, such as may occur in working with Diesel engines. In these engines the fuel is forced through fine jets at pressures as high as 6,000 pounds per square inch in order to produce finely divided particles for rapid combustion. At such pressures the fine spray may penetrate the skin and cause injury to the subcutaneous tissues. In the case reported by Rees the accident resulted, in twenty-four hours, in intense pain and marked swelling of the affected finger and the hand. Gangrene of the finger followed and amputation through the metacarpal bone became necessary. The cases to be reported here were similar in several respects; namely, the severe pain, the gangrene and the sterile necrosis involving the skin and especially the subcutaneous tissues.

REPORT OF CASES

CASE 1.²—An engineer brought the tip of his index finger in contact with a fine jet of oil coming from a Diesel engine injector under high pressure. The finger immediately ballooned out like a sausage, and the patient milked oil out of the little puncture in the end of his finger. He was seen immediately after the accident, but nothing showed objectively except moderate swelling of the finger and a punctate wound at the tip of the distal phalanx. That night more swelling developed, with intense pain in the finger. Still later the swelling increased, with a somewhat livid discoloration of the whole finger. The

patient was hospitalized and deep linear incisions were made on both lateral aspects of the phalanges.

The end result was that the entire distal phalanx became necrotic and was amputated; also the flexor profundus tendon sloughed. A peculiar condition developed in that for weeks after the amputation small pieces of wax kept being extruded from the stump.

The patient has a moderately useful finger but some circulatory impairment has persisted.

CASE 2.—An engineer, aged 44, while testing the fuel injectors of a Diesel engine, inadvertently put his hand in front of the injector and the spray struck the volar surface of the left index finger. When he was seen less than an hour later there was very little swelling and the color of the finger was not abnormal. There were three minute puncture wounds on the volar surface of the distal phalanx but no bleeding. There was moderate pain. The distal end of the finger was blocked with procaine hydrochloride and two parallel longitudinal incisions were made over the volar surface, a sterile dressing was applied and the patient was allowed to go home. Seven hours later the pain was so severe that one-fourth grain (0.015 Gm.) of morphine was given, with partial relief. Twenty-four hours after the injury the pain had diminished but was still severe. The color of the finger was satisfactory. There was very little drainage. A hot magnesium sulfate soak was given and the patient was instructed to repeat this treatment at four hour intervals at home. Forty-eight hours after the injury there was a bluish discoloration of the pulp of the finger and of the subungual tissue. There was less pain than before. Sensation to pinprick on the volar surface was diminished. The picture was that of incipient gangrene. Oscillometric readings showed a definite decrease in the ulnar and radial pulses as compared with those of the uninjured hand. The patient was therefore hospitalized at once and positive-negative pressure treatments (passive vascular exercise) were given for three hours twice a day. The finger became more comfortable with this treatment and the temperature, which was never more than 38 C. (100.4 F.), became normal in two days. The color of the finger also improved, but only temporarily. On the eleventh day after the injury the finger tip was again discolored and, although there was no pain or elevation of temperature, there was definite fluctuation. A fish-mouth incision was made, therefore, liberating a small amount of purulent material which showed no growth on culture. The subcutaneous tissue was gray and necrotic. Bare bone was not exposed. Hot moist dressings were applied for several days and after two days, when a negative culture was reported, the passive vascular exercise treatments were resumed. After the incision and drainage the general color of the finger improved, but the small area of skin between this incision and the one made on the day of the injury became gangrenous and was removed. The wound slowly filled in and was healed in two months from the onset. The passive vascular exercise treatments were continued until discharge from the hospital a month after admission.

Examinations of the blood and urine showed nothing unusual. A roentgenogram of the finger on the fifth day of the disease showed no evidence of pathologic changes of the bone.

This patient also has a useful finger, although there is almost no motion in the distal interphalangeal joint.

An attempt was made to determine the nature of this type of injury by injecting small amounts of the fuel oil beneath the skin of a rabbit's ear. Injections of oil varying in amount from 1 minim (0.06 cc.) to 1 cc. were made. In each case a sterile abscess formed without the local heat and redness usually associated with infections. It is assumed that the oil is in itself toxic, producing a reaction similar to that caused by turpentine.

The logical treatment, as suggested by Rees, would seem to be early and liberal incision. In case 1 the incision was probably delayed too long. In case 2 incision was done early but was perhaps not adequate in extent. The value of passive vascular exercise is hard to determine, though it seemed to be of some value in this instance. It deserves trial on the basis of the associated arteritis or arterial spasm which was shown to be present in one case.

DERMATITIS FROM THE USE OF DRY SHAVERS

HAROLD SHELLOW, M.D., CHICAGO

In recent years dry shaving methods have been widely popularized and in many instances they have been adopted to minimize the amount of irritation of the skin. It is my purpose to report three cases of dermatitis resulting from the use of dry shavers. Since this paper was written, four additional cases have come to my attention.

REPORT OF CASES

CASE 1.—A young man who had been using a round-head type of dry shaver for a month noticed an eruption on his face. This started with a burning and redness of the skin, which came on several days after he had used the new method of shaving. At first the reaction lasted for a few hours but, with continued use of the implement, the rather transient inflammation gave way to a permanent redness and scaling around the hairs. He stated that he had used the shaver over and over again in order to obtain a shave as close as he had accomplished with the ordinary variety of razor.

He had a pinhead to small pea sized erythematopapular eruption, in the main about the hair follicles but also present interfollicularly. Fine scaling accompanied the eruption and a few scattered pustules were seen. The lesions were distributed over the bearded areas of the cheeks and the sides of the chin and in small patches on the upper front part of the neck.

In four days after an ordinary razor was substituted and a bland lotion prescribed, the eruption began to fade; no pustules were seen and six days later, except for a faint reddish tinge, the skin was normal. Two weeks after the dermatitis disappeared, on resumption of shaving with the electric razor, burning, tingling and redness came on, followed in two days by duplication of the former condition. No after-shaving lotion had been used. Patch tests with the razor head and soap were negative.

CASE 2.—A man, aged 22, who had had a clear skin until about a week after he started using a dry shaver (flat-head type), complained of a transient burning and redness of the face which was followed by an eruption. An ordinary face soap had been used and, except for talcum powder, no after-shaving preparation had been applied. The eruption involved the bearded areas of the face and consisted of erythematous papules ranging from the size of a pinhead to slightly larger. These coalesced to produce irregular patches with small islands of normal skin intervening. In the follicular areas the papules were of a deeper reddish hue and occasional pustules and crusts were seen.

With discontinuance of the dry shaver, the substitution of an ordinary razor and the use of bland medication, all subjective symptoms vanished in three days, and in two weeks the skin was back to normal. Seen again a month later, the patient stated that he had tried the electric razor for a few days in succession but had experienced burning and redness of the skin and had been compelled to stop using the shaver.

CASE 3.—A young woman complained of a rash on her legs which was accompanied by burning and itching. The day before the eruption appeared she had used a dry shaver to remove the hair on her legs. She readily admitted that she went over the skin time and again in order to remove the short stubbles of hair. The eruption consisted of pinpoint to pinhead sized maculopapules of bright red hue, hemorrhagic in nature. It involved the anterior, medial and lateral aspects of the lower extremities from below the knees to about the lowest one third of the legs.

Three days after the first appearance of the eruption the follicular lesions became darkly crusted, and a week later only residual redness remained. Six weeks later she again used a dry shaver, this time a different variety, but the following day the skin broke out as it had before. Patch tests with the shaving heads were negative.

COMMENT

In the presence of an eruption, the dry shaving method has often been usefully employed to reduce the amount of irritation of the skin. Under normal conditions two factors are offered

as an explanation of the dermatitis: First, the lack of preparation that accompanies the use of the dry shaver may lead to neglect of washing the skin, thereby increasing the likelihood of infection. Second, and conceivably the essential one, there is traumatization, which results from the desire to obtain as close a shave with the dry shaver as with the ordinary razor. Observations have shown that this is almost impossible to achieve but, in an attempt to do so there is a tendency to cause constant manipulation or overuse of the device, as illustrated by the cases here reported. The vigorous application leads to trauma by virtue of the fact that the head of the shaver is "massaged" on the skin, thereby producing irritation, which leads to the dermatitis.

These cases are few in number, but with the multitude of users it must follow that many cases similar to these have and will occur, and this may serve as a means of calling attention to the possible source of cutaneous manifestations that the dry shaving method may produce.

Special Article

THE CHEMISTRY OF VITAMIN A
AND SUBSTANCES HAVING
A VITAMIN A EFFECT

L. S. PALMER, PH.D.

Professor of Biochemistry, University of Minnesota
Department of Agriculture

ST. PAUL

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Shortly before the late Dr. Lafayette B. Mendel wrote an article on vitamin A for the previous vitamin symposium in *THE JOURNAL*, the perplexing question as to why the yellow-red plant pigment carotene exhibits vitamin A activity although the familiar vitamin A of liver oils is essentially a colorless substance had been answered by the discovery¹ that carotene is convertible in the body to vitamin A. In fact the chemical basis for such a relationship had just been established by the brilliant researches of Karrer and his associates, who had determined the chemical constitution both of plant carotene² and also of vitamin A³ from fish liver oil.

The first complete structural formula for carotene (fig. 1) has since turned out to be that of β -carotene, which is by far the most important and widely distributed of the known coloring matters which have vitamin A activity.

β -carotene is a nitrogen-free, aliphatic, methylated polyene having two identical, unsaturated, methylated terminal rings. (The term polyene is given to compounds having a series of conjugated double bonds.)

1. Moore, Thomas: Vitamin A and Carotene: V. The Absence of the Liver Oil Vitamin A from Carotene; VI. The Conversion of Carotene to Vitamin A in Vivo, *Biochem. J.* 24: 696 (No. 3) 1930; The Distribution of Vitamin A and Carotene in the Body of the Rat, *ibid.* 25: 275 (No. 1) 1931.

2. Karrer, P.; Helfenstein, A.; Wehrli, H., and Wettstein, A.: Pflanzenfarbstoffe: XXV. Ueber die Konstitution des Lycopens und Carotins, *Helv. chim. Acta* 12: 1084, 1930.

3. Karrer, P.; Mori, R., and Schöpp, K.: Zur Kenntnis des Vitamins A aus Fischtranen II. *Helv. chim. Acta* 14: 1431, 1931.

When the aliphatic central chain is examined more closely it may be considered as a condensed chain of four dehydrated isoprene (β -methylbutadiene) residues, shown in the diagram between the broken vertical lines. It will also be noted that these isoprene residues are arranged in pairs, which are united in reverse order at the carbons 15, 15'.

The discovery of this fact by Karrer and his associates is important to an understanding of the relation of carotene to vitamin A because the double bond uniting the two pairs of reversed isoprene residues is evidently capable of hydrolysis giving rise to an alcoholic group in each of the split products. This is the only known basis for the formation of vitamin A from those carotenoids which, in addition to the same polyene chain, also possess, at one or both ends of the structure, the same rings possessed by β -carotene.

In keeping with these facts, Karrer and his associates proposed the structure for vitamin A shown in figure 2, which is now generally accepted.

The ring structure in both β -carotene and vitamin A proved to be of great importance for establishing the structural and the chemical relationships of these substances. The ingenious researches of Karrer were the first to prove that β -carotene contains two β -ionone rings, β -ionone having the structure shown in figure 3.

When this structure was demonstrated in carotene it was relatively easy to demonstrate its occurrence in a highly purified vitamin A preparation from fish liver

α -carotene has one β -ring and one optically active α -ring; γ -carotene has only one ring, a β -ring, the other potential ring being open, and cryptoxanthin has one β -ring and one β -oxidized ring. γ -carotene, being a monocyclic compound, is related both to carotene and to lycopene, the familiar red tomato pigment, which is a noncyclic hydrocarbon having both potential β -ionone

Vitamin A

Fig. 2.—Structure of vitamin A.

rings open. As previously stated, β -carotene is much the most important of the four known vitamin A precursors, α -carotene and, especially, γ -carotene and cryptoxanthin having a limited distribution in the natural foodstuffs of man and animals.

In several of the best known and most widely distributed carotenoids, one or both of the terminal rings have one or more alcohol ($=\text{CHOH}$) groups, as already mentioned for cryptoxanthin, or they may have one or more ketone ($=\text{CO}$) groups. Astacin (astacene), the familiar red pigment of lobster and salmon, is a tetraketone- β -carotene. It is a curious fact, however, that the part of a carotenoid molecule possessing the α -ionone ring or its alcohol or ketone derivatives or containing the alcohol or ketone derivatives of the β -ionone ring is not convertible in vivo to vitamin A. As carotenoids which have no ring structure, such as lycopene, capsorubin (capsorubene), bixin (bixene) and crocetin (crocetene), have no vitamin A activity, as is the case for one-half the molecule of γ -carotene, previously referred to, it is concluded that the intact β -ionone ring is an essential component of the vitamin A molecular structure. It is further concluded that each molecule of β -carotene is capable of giving rise to two molecules of vitamin A, while α -carotene, γ -carotene and cryptoxanthin may give rise to only one vitamin A molecule. It is further concluded that no other carotenoid⁸ whose structure has been determined is a potential vitamin A precursor.

The carotenoids possessing alcohol-containing or ketone-containing ionone rings are much more abundant in nature than are the carotenes. Several of these carotenoids were formerly classed together under the general term xanthophyll because of their characteristic yellow color. Of the many xanthophylls (?) now known, only one is still called xanthophyll, more specifically plant xanthophyll (sometimes called lutein); it is a dioxy- α , β -carotene. Earlier reports of vitamin A activity of crystalline plant xanthophyll were not confirmed and would not have been expected to be confirmed had the chemical relationships been established between the carotenes and vitamin A.

Most of the pigments formerly classed as xanthophylls now carry a specific name ending in -xanthin, such as zeaxanthin, the dominant pigment of yellow corn, also

 β -caroteneFig. 1.—Structure of β -carotene.

oil. Soon Heilbron, Morton and Webster⁴ were able to substantiate Karrer's formula by forming a naphthalene compound from vitamin A which one could account for only by assuming the correctness of Karrer's formula. Also, Karrer⁵ himself completed the proof by an eight step synthesis of crystalline perhydrovitamin A (the completely hydrogenated derivative of the highly unsaturated compound), beginning with β -ionone and proving its complete chemical identity with the similarly crystalline hydrogenated natural vitamin from fish liver oil.

The final step in this chemical story is the synthesis of the pure vitamin in vitro. Recent reports⁶ indicate that this has been accomplished. The isolation of the crystalline natural vitamin has also been reported.⁷

The ring structure in vitamin A is of great biochemical importance. Not only does it play an as yet undetermined role in the biologic activity of the vitamin but it has also been demonstrated that of the thirty or more carotenoids whose chemical structure now seems well established only four may be converted in vivo to vitamin A; likewise, only these possess the optically inactive β -ionone ring. Of these four vitamin A precursors only β -carotene has two such rings;

 β -iononeFig. 3.—Structure of the β -ionone ring.

8. A possible exception is echinenone, a carotenoid from the sea urchin (Lederer, E., and Moore, T.: Echinenone as a Provitamin A, *Nature* **137**: 996 [June 13] 1936).

found in green leaves; capxanthin, the dominant pigment of the red peppers, paprika and pimento; fucoxanthin, the dominant pigment of the so-called brown algae; flavoxanthin, the buttercup pigment; violaxanthin, from the yellow pansy, and taraxanthin, from the dandelion.

Table 1 shows some of the more important carotenoids, their chief occurrence in nature and their relation to vitamin A.

The aliphatic primary alcohol structure of vitamin A is important also in connection with its biochemical properties. It allows for esterification and therefore for compounds of vitamin A with fat acids, proteins and bile acids, which would not be possible for any of the known carotenoid precursors of the vitamin except cryptoxanthin, which, as already stated, has an alcohol group on one of its ionone rings. The alcohol groups on the ionone rings are also capable of ester formation;

TABLE 1.—A Partial List of Carotenoids, Their Important Sources and Their Relation to Vitamin A*

Name	Sources	Molecules of Vitamin A Possible from One Molecule of Pigment
α -carotene.....	Red palm oil, chestnuts, carrot root, mountain ash berries.....	1
β -carotene.....	Green leaves, carrot root, red palm oil, butter.....	2
γ -carotene.....	Fruits of <i>Gonocaryum pyriforme</i> (a Dutch East Indies plant), leaves of lily-of-the-valley.....	1
Cryptoxanthin.....	Red calix and fruit of the Chinese lantern plant, yellow corn, egg yolk, green grass.....	1
Xanthophyll (luteln)	Green leaves and grass.....	0
Zeaxanthin.....	Yellow corn, green leaves, egg yolk....	0
Rhodoxanthin.....	Seed coat of the yew.....	0
Astacin.....	Lobster, salmon, shrimp.....	0
Lycopene.....	Red tomato, watermelon.....	0
Capxanthin.....	Red peppers, paprika, pimento.....	0
Fucoxanthin.....	Brown algae.....	..
Taraxanthin.....	Dandelion, sunflower, cocksbur.....	0
Violaxanthin.....	Yellow pansy.....	0
Flavoxanthin.....	Buttercup.....	0

* The carotenoids mentioned are not necessarily the exclusive cause of the pigmentation of the products mentioned. In most cases they are not. Of the vitamin A active products, red palm oil and carrots contain chiefly β -carotene and α -carotene and butter chiefly β -carotene, and of the carotenoids in green leaves, β -carotene is found almost exclusively, although xanthophyll and zeaxanthin are the dominant carotenoids.

in fact, the carotenoids which possess such structures apparently exist in nature as esters rather than as free pigment. Various fat acid esters of vitamin A have been described, and there is evidence to indicate that the vitamin is absorbed as bile acid compound,⁹ transported in the blood and lymph as fat-acid ester¹⁰ and stored in the liver as a similar compound.¹¹ This suggests that the vitamin performs its biochemical function in chemical combination with other substances rather than as free substance. Support for this theory

Soc. argent. de biol.* **11**: 283 (July) 1935; Sur l'état de combinaison de la vitamine A dans les huiles de foie, *Compt. rend. Soc. de biol.* **120**: 577 (No. 33) 1935.

is found in the experiments of Wald,¹² which point to a close chemical relationship between the visual purple (rhodopsin) of the retina and a protein-vitamin A compound, which offers a chemical explanation for the well known importance of vitamin A in certain of the visual processes, including its role in the correction of idiopathic hemeralopia.

Vitamin A compounds are decomposed, with the liberation of the vitamin, by such hydrolytic processes as occur in saponification, although the vitamin, being an alcohol, is not itself saponifiable. Most of the carotenoids, as their structure indicates, are also non-saponifiable. Therefore the vitamin A precursors, together with any vitamin A, appear in the non-saponifiable extracts of fats and oils that contain them. This is the basis of the manufacture of the so-called cod liver oil "concentrates." Because of its alcoholic nature, vitamin A may be separated from its carotenoid precursors by the "phase-separation" test, by which a petroleum ether (low boiling) solution of the mixed products is shaken with 80 to 90 per cent methyl alcohol. The alcohol will extract the vitamin A from the immiscible upper layer of petroleum ether, leaving behind all its carotenoid precursors.

Consideration must be given the possible importance of the unsaturated bonds in vitamin A. Four of these are present in the aliphatic side chain and one in the ionone ring. Perhydrovitamin A and perhydro- β -carotene, which are completely hydrogenated substances, have no biologic activity, but both α -dihydrocarotene and β -dihydrocarotene are active,¹³ as is also di-iodo-carotene. The double bonds eliminated when the last-named by-product is formed are solely in the side chain. However, it is not entirely clear whether the relation of unsaturation to physiologic activity resides solely in the β -ionone ring or whether some unsaturation in the side chain is also important. It is certain of course that the side chain unsaturation explains for the most part the probable function of vitamin A as oxidation reduction catalyst, also possessed by the carotenoids. The unsaturated bonds explain the action of both vitamin A and its precursors as hydrogen acceptors, and experimental evidence has shown that the substances readily absorb oxygen in solution and are markedly pro-oxygenic when undergoing oxidation. Highly oxidized carotenes and vitamin A have no biologic activity, a fact of great importance in the preservation of the vitamin A activity of foods and medicinal products. Hydroxyphenolic compounds, such as hydroquinone and vitamin E, exert some protective action against the oxidation of carotenes and vitamin A. Vitamin A and its precursors are stable to the usual cooking and heat-processing procedures provided they are protected against oxidation.

Vitamin A and its precursors exhibit characteristic differences in their affinity toward various adsorbents, such as calcium carbonate and alumina (aluminum oxide). When a petroleum ether solution of the mixture is filtered through a tightly packed column of finely powdered aluminum oxide, the order of decreasing adsorption affinity will be γ -carotene > cryptoxanthin > β -carotene > α -carotene > vitamin A. This property has been very useful in the isolation and study of the carotenoid precursors of vitamin A.

13. von Euler, H.; Karrer, P.; Hellström, H., and Rydberg, M.: Die Zuwachswirkung des isomeren Carotins und ihrer ersten Hydrierungsprodukte, *Helv. chim. Acta* **14**: 839, 1931.

Each of the vitamin A active carotenoids shows characteristic absorption bands in the visible (blue and violet) region of the spectrum. The exact position of these bands depends on the index of refraction of the solvent employed, and their intensity depends on the molar concentration of carotenoid in the layer through which the light passes. Spectroscopic absorptions of much less intensity occur in the ultraviolet, which may be detected by photographic methods. The wavelengths of maximum absorption of the two most prominent visible bands of the vitamin A active carotenoids in carbon disulfide solution are shown in table 2.

Vitamin A differs from its precursors in showing no absorption bands in the visible region of the spectrum. Instead it shows a rather broad absorption region in the ultraviolet, with a definite maximum at 328 millimicrons in chloroform. These spectroscopic properties form the basis for the spectrophotometric methods for the quantitative estimation of vitamin A and its precursors.

All substances having the polyene structure give color reactions with numerous reagents, most of which are either strong acids or chlorides of polyvalent metals. The intense blue reaction with antimony trichloride given by the carotenes and the blue-violet color given with the same compound by vitamin A have been studied extensively. They serve to reveal the presence of vitamin A and its precursors in animal tissues and products and form the basis of carefully developed quantitative colorimetric methods, especially for preliminary assays of cod liver and other fish liver oils rich in vitamin A, and for exploratory research in the physiology of the vitamin.

The spectroscopic properties and color reactions mentioned will no doubt be discussed in greater detail in another paper in this series dealing with methods of assay.

Although the chemical and physiologic relations between vitamin A and its precursor carotenoids have been well established, the conversion of the latter to the former has not yet been accomplished by chemical procedures. All evidence points to the liver as the site of the formation of vitamin A in animals, presumably by means of an enzyme, which has been called carotenase. Earlier reports¹⁴ of demonstration of this action in vitro have not been confirmed. It is clearly unnecessary for man or animals to make this conversion when vitamin A is provided per se in the diet. Indeed, question has been raised as to whether all species¹⁵ are able to form vitamin A from carotene. Marked differences between species no doubt occur with respect to the efficiency of conversion of carotene to vitamin A. It is known that considerable of the ingested carotene occurs in the blood and is deposited in adipose tissue in man, the cow and the horse; in the cow, for which the problem has been studied, a relatively small proportion¹⁶ of ingested carotene is absorbed and converted into vitamin A. Some breeds, such as the Guernsey, convert a smaller proportion of absorbed pigment than others, thus accounting for the larger proportion of

carotene than of true vitamin A in their milk fat in contrast to Holstein milk fat, which is lower in carotene but richer in true vitamin A.

Although color is one of the outstanding properties of the vitamin A precursors, in contrast to the essentially colorless vitamin A, some common human foods of animal origin which are not vitamin A precursors are often highly pigmented with carotenoids. For example, the yolk of hen eggs is normally poor in carotene but rich in zeaxanthin and xanthophyll. Normally it contains also vitamin A itself, owing to its formation in the fowl from the vitamin A precursors absorbed from the ration, as well as to the practice of adding fish liver oil to the ration. The carotenoid precursors of the vitamin occurring in egg consist largely of cryptoxanthin,¹⁷ especially when the hen is fed heavily on yellow corn or grass.

There is much more relation between color and potential vitamin A activity of the common vegetable foods consumed by man than between color and vitamin A activity of animal tissues or products of animal metabolism. Green and yellow (or orange) are the color indicators of potential vitamin A in plants, the former because carotenes always accompany the green chlorophylls. Natural yellow color may be a rough qualitative guide for selection of vitamin A active

TABLE 2.—Wavelengths of Maximum Absorption of Carotenoids

Carotenoid	Absorption, Mm.	Maximum, Mm.
γ -carotene.....	533.3	496.0
β -carotene.....	521.0	485.0
Cryptoxanthin.....	518.0	483.0
α -carotene.....	509.0	477.0

animal products, because it indicates the consumption of carotenoids and vitamin A precursors by animals even though the carotenoid which colors the product is not a vitamin A precursor. However, all fatty animal products are apt to contain some vitamin A itself if the animal is a transformer of carotene to vitamin A, regardless of the color of the product; some products may be exceptionally rich in true vitamin A and relatively poor in pigment. Certain of the fish liver oils have this characteristic, notably that of the halibut and the burbot.

In connection with any consideration of the relation between color (carotenoid) and vitamin A activity it should be remembered that vitamin A is the only vitamin so far discovered which is a product solely of animal metabolism from precursors which are metabolic products only of plants. This should not be lost sight of in spite of the fact that pure β -carotene is the international vitamin A standard, 1 international unit being the growth-promoting activity in rats of 0.0006 mg. of the standard β -carotene.

For a much more extensive discussion of the chemistry of vitamin A and the substances having the effect of vitamin A than is possible in this article the reader is referred to the extensive paper by Karrer and Wehrli¹⁸ and the monograph of Zechmeister.¹⁹

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

HOWARD A. CARTER, Secretary.

PEERLESS ULTRA SHORT WAVE UNIT, MODEL UW2M, ACCEPTABLE

Manufacturer: Peerless Laboratories, Inc., 115 East Twenty-Third Street, New York.

The Peerless Ultra Short Wave Diathermy, Model UW2M, is recommended for medical and surgical use. According to the firm, it has the same circuit and same identical electrical characteristics as the accepted Peerless Unit, Model UW2A (described in THE JOURNAL, Feb. 20, 1937, p. 639) except for the fact that the number of input control steps has been changed from five to nine and that the style of the cabinet has been altered.

The unit is equipped with terminal outlets to permit the use of inductance cable, air-spaced treatment arms, cuff electrodes, metal orificial electrodes and electrosurgical accessories for cutting and coagulation. The electrical design permits the use of all these modalities from one pair of terminals with no switching devices being used.

The wavelength is approximately 6 meters in this two-tube machine, which utilizes a self-excited, push-pull oscillator circuit. The patient's circuit is inductively and capacitatively coupled to the oscillator circuit. Tuning of the patient's circuit is accomplished with a double condenser with plates moving parallel, which tune the two branches of the patient circuit simultaneously. For consistency of performance and maximum life to tubes and other component parts, a switching arrangement is incorporated in the machine which enables the physician to adjust the operating voltages on filament grid and plate to line voltage variations within a range of from 105 to 135 volts in the power supply line.

A two-circuit line switch is employed as follows: First stage supplies the current to the filament and in the second stage connects the supply to the plate current of the tube. The physician is not likely to make any error in switching on the currents, as the rotation is automatic. This avoids shock to the tube which results from simultaneous application of the two currents. It also permits the use of a foot switch in the plate circuit only while the filament circuit is on, which is preferable for surgical use.

When this unit is operated under full load, it draws not more than 1,200 watts from the 60 cycle, 115 volt alternating current supply line and delivers about 540 watts. The output was determined by means of a pair of metal plates attached to the terminals of an incandescent lamp. These plates are provided with a suitable condenser to permit tuning to resonance. The light output of the lamps or the energy delivered to them is measured by means of a photronic light sensitive cell, connected to a sensitive micro-ammeter. No claim is made by the firm that this type of measurement constitutes an exact equivalent of power available for therapeutic purposes.

The temperature rise of the transformer, after the machine had been operated at full load for two hours, was 32 C. Other temperatures in the cabinet were in proportion. The maximum rise is above the oscillating tubes. This rise was 42 C. Burns may be produced with this as with any other short wave unit but may be avoided by the use of ordinary precautions. The weight is about 160 pounds.

The original accepted model was submitted for use with cuff electrodes. In addition, the new model offers inductance cable and air spaced technics. The firm submitted evidence relative to the latter two technics, since it was felt that the cuff technic would give results similar to those with the already accepted model. The new tests were performed by an investigator acceptable to the Council.

Two male students, weighing 150 and 165 pounds respectively, were the subjects. A cannula was introduced at the midpoint of the thigh and inserted for a distance of two inches or until the bone was encountered. Temperature readings were made by means of thermocouples inserted into the cannula. The thermocouples were constructed by placing constantan and copper wires into the end of a hypodermic needle. The copper constantan junction was kept at 0 C. by means of a vacuum bottle full of crushed ice. The couples were calibrated against a mercury thermometer certified and calibrated by the National Bureau of Standards. Potential differ-

Schematic diagram of circuit.

ences were read from a Leeds and Northrup portable potentiometer of requisite sensitivity. The accuracy was believed to be within one tenth of a degree.

The air-spaced electrodes were from 1¾ to 2 inches from the skin, and 9 inches apart from center to center. They were curved.

Averages of Six Observations, Air-Spaced Technic, with 5 Inch Diameter Electrodes

Temperatures			
Deep Muscle		Oral	
Initial	Final	Initial	Final
99.1	105.7	98.7	99.2

Averages of Six Observations, Cable Technic

Temperatures			
Deep Muscle		Oral	
Initial	Final	Initial	Final
98.9	104.7	99.3	99.8

When testing with the cable technic, approximately four turns of the cable were used, spaced approximately 1¾ inches apart, center to center. The distance between the coil and the thigh was spaced approximately 1¼ inches with felt, towel-ing or wooden spacers.

Evidence has been submitted with regard to pelvic heating. The technic for pelvic heating consisted in using a metal vag-

Peerless Ultra
Short Wave
Unit, Model
UW2M.

inal electrode with a hollow stem holding a thermometer and a large condenser pad placed on a shelf about 6 inches from the patient's sacrum. Treatment was administered to comfortable tolerance of the patient. In the series of eleven cases treated in the foregoing manner, the average final temperature was 107.5 F.

The unit was tried out in a clinic acceptable to the Council and rendered satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Peerless Ultra Short Wave Unit, Model UW2M, for inclusion in its list of accepted devices.

RADIOEAR ACCEPTABLE

Manufacturer: E. A. Myers & Sons, 306 Beverly Road, Mount Lebanon, Pittsburgh.

The Radioear consists of a microphone, intensifier and receiver (for bone and air) with the necessary connecting cords. It is assembled in the laboratory at Pittsburgh from duplicates of the patients' own selection of component parts with the use of the firm's Selex-A-Phone. This is essentially a "master hearing aid" with which the patient can try many or all of the various combinations of microphones, intensifiers and receivers (both bone and air) and under various voltages. These combinations are cut in or out by means of knobs and switches.

In order to purchase this type of hearing aid, the customer first has an analysis of his hearing aid requirements made by the Selex-A-Phone. Then the results of these tests are sent to the factory in Pittsburgh, where the characteristics of the original analysis of hearing aid requirements are matched in the acoustical laboratory maintained by the manufacturer. To accomplish this the separate components of the hearing aid are adjusted, prior to the overall adjustment, to which certain specified tolerances. These parts are then tentatively assembled, and the final matching and aligning of the hearing aid to the

(1) Radioear De Luxe Model.

(2) Selex-A-Phone.

desired characteristics is performed on the hearing aid as a whole. The composite or overall alignment is considered by the manufacturer to be an important part of the construction of the hearing aid. After the laboratory has determined that the completed instrument meets the required specifications, it is forwarded to the office from which the order originated and the patient may compare its amplification characteristics with those of the Selex-A-Phone by which the analysis of hearing aid requirements was originally made.

The manufacturer states that his responsibility does not end when the individual has satisfied himself that the finished instrument has the desired characteristics. The customer has the option at any time within thirty days from the date of delivery of selecting any other hearing aid characteristic available on the Selex-A-Phone which he may find is more suitable for his requirements. This privilege is made available to the customer regardless of the fact that his subsequent decision may entail the supplying of an entirely different type of hearing aid. These changes may involve different characteristics for every component part of the hearing aid. When these alterations are made, they involve rebuilding the hearing aid to the new characteristics in the laboratory. The size, weight, amplification characteristics and appearance of the resulting instrument may be radically different from the original selection. Under this policy, if any error in the original selection has been made, or if the customer finds another characteristic more desirable, the firm then assumes the obligation of rebuilding the hearing aid free of charge. At the end of the thirty day period, the hearing aid is not returnable for full credit. The firm deducts \$35

from the purchase price to cover expenses incurred in assembling and testing the individual instrument at the laboratory.

Those units fitted by means of the Selex-A-Phone and coming to the attention of the Council's investigator appeared to give satisfactory service. The point is stressed by the firm that these instruments are all laboratory built.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Radioear Hearing Aid for inclusion in its list of accepted devices.

Council on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

NUTRADIET FRESH GREEN ASPARAGUS PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned asparagus, packed in water without added sugar or salt.

Manufacture.—Asparagus on which no insecticide spray has been used is graded for size and quality and only the larger spears are retained. They are cut to 4 inch lengths, washed in running water, blanched, dipped in cold water, and a definite number of spears are packed in each can, which is weighed also. Water is added and the containers are exhausted, sealed and processed. The asparagus is in cans within six hours after it is cut.

Analysis (submitted by manufacturer).—Moisture 93.3%, total solids 6.7%, ash 0.4%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 2.8%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 2.7%.

Calories.—0.24 per gram; 7 per ounce.

Claims of Manufacturer.—For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED BEETS

Manufacturer.—Stokely Brothers & Company, Indianapolis.

Description.—Strained beets, seasoned with salt, retaining in high degree the natural vitamin and mineral content.

Manufacture.—Selected, fresh tender beets are thoroughly washed and inspected, steamed in a closed kettle, peeled, sieved in a steam atmosphere, salt is added, and the product is canned and processed as described for Stokely's Strained Green Beans (THE JOURNAL, May 26, 1934, p. 1763).

Analysis (submitted by manufacturer).—Moisture 85.7%, total solids 14.3%, ash 1.2%, sodium chloride 0.54%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 1.4%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 10.9%, alkalinity number (cc. normal acid per gram ash) 16.4.

Calories.—0.5 per gram; 14 per ounce.

Vitamins.—The natural vitamin content is claimed to be retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air.

VALLEY LEA BRAND EVAPORATED MILK

Manufacturer.—Producer's Creamery, Marion, Ind.

Description.—Unsweetened, sterilized, evaporated milk.

Manufacture.—Milk from company inspected farms is tested, preheated, evaporated, homogenized, cooled, standardized, filled into cans, sealed, and sterilized.

Analysis (submitted by manufacturer).—Moisture 73.8%, total solids 26.2%, ash 1.6%, fat (ether extract) 8.2%, protein ($N \times 6.38$) 7.0%, lactose (by difference) 9.4%.

Calories.—1.4 per gram; 40 per ounce.

SATURDAY, MAY 21, 1938

POLIOMYELITIS INFECTIVITY OF HUMAN STOOLS

The recent isolation of the virus of poliomyelitis from human feces¹ is presumably additional evidence that viable virus can pass through the gastrointestinal tract. There is as yet no experimental evidence that this virus proliferates in the intestine. Nevertheless, identification of the virus in human stools suggests that certain precautions should be taken that are now generally considered unnecessary.

Following the successful transmission of poliomyelitis to monkeys, tests were made as early as 1912 of the infectivity of fecal poliomyelitic material. Kling, Pettersson and Wernstedt² of Stockholm, Sweden, reported the successful inoculation of monkeys by the intracerebral injection of colonic washings from infants during both the acute and the convalescent period of infantile paralysis. This result was confirmed three years later by Sawyer.³ Since lethal paralytic effects can be produced by control intracerebral injection of normal fecal extracts, this earlier apparently successful isolation and identification of the virus in human stools was generally discredited.

Last year, Harmon⁴ repeated these early tests under adequately controlled conditions and was able to isolate and identify poliomyelitis virus in the stools of four of twenty patients tested. The most convincing evidence of intestinal infectivity, however, is currently reported by Dr. J. D. Trask¹ and his co-workers of the department of pediatrics at Yale University. The Yale pediatricians tested fecal infectivity by the less toxic method of intraperitoneal injection in monkeys. In their technic, 120 cc. of distilled water was added to the whole stool of the infant and the mixture agitated and allowed to stand for two hours at room temperature. The supernatant fluid (90 cc.) was then pipetted off into a rubber stoppered flask and

partially sterilized by the addition of 15 per cent ether (U. S. P.). After storage for twenty-four hours at refrigerator temperature, 30 cc. of the etherized supernatant fluid was injected intraperitoneally into monkeys. As an alternate method the ether was removed and the fluid reduced to about a tenth of its original volume by vacuum distillation. This concentrate was also to be used for control intracerebral injections. Of the eleven monkeys thus far injected intraperitoneally with the etherized supernate, but one developed peritonitis and bacteremia.

By this intraperitoneal technic the Yale pediatricians successfully recovered viable poliomyelitis virus from the stools of an 18 months old infant on the second, fourteenth and twenty-fifth days of the disease. Monkeys thus inoculated usually had typical paralytic symptoms on the seventh day. Paralytic symptoms and histologic lesions were characteristic of experimental poliomyelitis in this animal. Successful passage to a second monkey was accomplished by routine technics. Additional work must be done, however, before a final interpretation of these results is possible.

THE EFFECT OF ANESTHETICS ON HEPATIC FUNCTION

The hazard of operative procedures in patients with diseased livers suggested the desirability of determining the state of hepatic function before subjecting such patients to the combined risk of anesthesia and operative trauma. Rosenthal and Bourne¹ have pointed out that the changes which anesthetics produce in the liver undoubtedly occur also in most other organs and are but a reflection of the widespread depression of cell activity resulting from certain anesthetics. The appraisal of the functional capacity of the liver is formidable because of the multiplicity and diversity of its functions. The various functional tests thus far available could do no more than reflect the state of one of these functions. A satisfactory answer to the query therefore could be reached only through study of several of the hepatic functions. There is, however, no correlation between the type of pathologic lesion present in the liver and the function that is disturbed. According to Soffer,² one positive test is as significant an index of the presence of damage as would be the case if all the tests were abnormal.

The excretion tests are based on the ability of the liver to remove from the blood stream certain dyes that are excreted in the bile. Bromsulphalein, a dye synthesized by White, was found by Rosenthal and White to be excreted rapidly in the bile. Eighty-five per cent could be recovered in the rabbit's bile within one hour after an intravenous injection. Normally the liver can remove this dye almost completely from the blood within fifteen minutes after injection, but if

the liver is injured the dye is not taken up and remains in the blood for a long time. The investigators found that the dye when injected in dogs in doses of 5 mg. per kilogram of body weight was no longer recoverable from the blood fifteen minutes after its injection. In their experiments on dogs, utilizing the bile pigment disturbances and the bromsulphalein test, they found that brief periods of anesthesia with chloroform are sufficient to produce both immediate and delayed toxic effects on the liver. Administration of chloroform for one-half hour causes injury that requires eight days for functional recovery; two hours of anesthesia requires six weeks for return to normal. Ether produces a definite but transitory impairment to function. Nitrous oxide and ethylene, administered through a mask, did not produce any change in the bromsulphalein test for hepatic function or any disturbances in the bile pigment. Nitrous oxide and ethylene given in a closed chamber with poor oxygenation caused both immediate and delayed toxic effects on the liver. Cyanosis in itself, they say, was found to increase the toxicity of anesthetics on the liver. The authors feel that ethylene would seem to be the anesthetic of choice for operation in cases of severe disease of the liver.

Robertson, Swalm and Konzelman³ concluded on the basis of their clinical studies in 118 cases that the bromsulphalein excretion test and the icteric index determination most frequently agree with the clinical picture. Coleman,⁴ in a recent communication, reports a series of one hundred surgical cases which were studied relative to the effect of anesthesia on hepatic function. The bromsulphalein dye excretory test was used, 10 per cent or less being accepted as a normal retention. It was found that avertin with amylene hydrate produces hepatic damage in a higher percentage of cases and to a greater degree than nitrous oxide, ether vapor anesthesia, nitrous oxide and oxygen, spinal, local, and open ether anesthetics. The liver is slower in recuperating from the damage produced by avertin with amylene hydrate than from the other four types of anesthesia which produced hepatic damage. Nitrous oxide and oxygen results in damage to the liver in a smaller percentage of the cases than nitrous oxide and ether vapor, and spinal anesthesia; however, the damaged liver from nitrous oxide and oxygen recuperates at about the same rate as the liver damaged by nitrous oxide and ether vapor. Local anesthesia did not produce liver damage. Avertin with amylene hydrate was found to be most toxic to the liver, and, in order of decreasing toxicity, nitrous oxide and ether vapor, spinal, nitrous oxide and oxygen, and local anesthesia. The longer the anesthesia and the older the patient, the greater will be the chances of hepatic damage from an anesthetic. If impaired function exists prior to the administration of anesthetics, it is a

certainly that additional damage to the liver will result. Coleman found also that patients with uncomplicated and smooth convalescence seldom gave evidence of hepatic damage. If a rise in the percentage of retention of the dye occurs after the first postoperative day, a complication will usually be found. Excluding infections of the liver and biliary tract, pulmonary tuberculosis, chronic sepsis and overwhelming infections, surgical cases with an associated infection such as acute appendicitis, abscesses and wound infections will not show evidence of impaired hepatic function resulting from the infection per se.

The need for a more or less standardized test for hepatic function has been felt for some time. Some of the unexplained deaths following operations for gall-bladder disease were no doubt due to grave impairment of the hepatic function. The van den Bergh test and the icteric index proved their value in the management of the jaundiced patient; in the absence of jaundice the bromsulphalein test is probably most valuable. In view of the enormous part played by the liver in various defense mechanisms of the body, the determination of its functional status might well be included as a routine procedure among preoperative biologic analyses.

OPERATIONS: FREQUENCY AMONG 9,000 FAMILIES

Scientific surgery has advanced greatly and the number of operations has increased vastly in the past fifty years. The extent to which this has occurred is perhaps not generally appreciated. Matas has stated that in 1881 there were 172 operations among 5,309 admissions to the Charity Hospital in New Orleans, and two thirds of these were of an emergency character. In the same hospital in 1923 there were 16,405 operations among the 20,565 admissions—a striking illustration of the growth of surgery. Similarly, according to Collins,¹ United States Army and Navy records indicate that there are now about twice as many operations per thousand men in those organizations as in 1910. There is no accurate information available on the annual number of surgical operations in the United States.

The frequency of surgery in a given population group may be expressed either as the annual number of surgical operations per thousand persons under observation or as the percentage of all cases of illness that were treated surgically. The recent study by Collins of the nature and frequency of operations is based on a nationwide periodic canvass of illness among about 9,000 families involving 38,544 person years of observation. This was the same group of white families in 130 localities in eighteen states which was studied by the Committee on the Costs of Medical Care and the United States Public Health Service. For the total 38,544

4. Coleman, F. P.: The Effect of Anesthesia on Hepatic Function, *Surgery* 3: 87 (Jan.) 1938.

1. Collins, S. D.: Frequency of Surgical Procedures Among 9,000 Families, Based on Nationwide Periodic Canvasses, 1928-1931, *Pub. Health Rep.* 53: 587 (April 22) 1938.

person years there were 2,623 surgical operations, or an annual rate (adjusted for age) of sixty-five operations per thousand persons. This crude rate gives a startling picture. If it were representative of the full picture it would mean that every individual, on the average, would have one operation approximately every fifteen years or would have four operations altogether, assuming a life expectation of sixty years. But this does not represent a correct interpretation of what actually occurs. The operations included both primary and contributory causes of illness and in a few instances two or more operations in connection with the same diagnosis. Furthermore, the age distribution of the group was such as to give a preponderantly youthful sample and a group which contained two distinct surgical peaks. There were, in fact, approximately twice as many individuals included in the survey between 25 and 45 as in the group of 45 and over, and more under 5 years of age than between 15 and 25, a significant deviation from the age distribution of the general population.

The surgical procedures listed included everything from a major abdominal operation to lancing a boil or removing a wart; of the sixty-five operations per thousand, eighteen were tonsillectomies and adenoidectomies, seven settings of bone and nearly six appendectomies. The surgical peaks were accounted for by the high incidence of tonsillectomy in the age period from 5 to 9 and by increased surgery for female genital and puerperal diagnoses from 30 to 34. If operations in connection with injuries are considered as a unit they amounted to 20.3 per cent of the total, and the group of female genital and puerperal operations to 8.3 per cent. When these two are added to tonsillectomy and appendectomy, the four fairly specific types of operations made up about two thirds of all the surgical procedures.

The proportion of operations done as an emergency was not large. Because of the large number of non-emergency operations, Collins says, one would expect more surgery among higher income groups in which funds are available for medical care that is not immediately necessary. For males, operations were about twice as frequent among professional and business men as among unskilled laborers; clerks and skilled laborers fell between these two extremes. Similarly, Collins found that the frequency rates of surgery varied from fifty-two operations per thousand persons in families of annual incomes of less than \$1,200 to ninety-four in families of \$5,000 or more income. The proportion of operations was also higher in large cities than in rural areas, and the persons in the lowest income group that live in large cities likewise obtained more surgical treatment than those in the rural areas of similar economic status. Finally, this study showed that 61 per cent of all operations in the group had some hospital care; the other 39 per cent were done in the office, clinic or at home.

This interesting study constitutes a survey of certain phases of surgery in relation to the whole problem of illness. Any one who studies the statistical information available from the survey may manipulate it in a different manner; in view of the defective nature of the sample, from the point of view of age alone, the conclusions which can be deduced legitimately are seriously limited. Furthermore, since many of the surgical procedures were apparently nonemergency in nature and possibly of the "luxury" type, sweeping inferences on the relation to economic status do not seem justified. Possibly the next canvass of this nature can be devised to overcome some of these objectionable features in this otherwise interesting and valuable study.

Current Comment

HEREDITY AND OPHTHALMOLOGY

The island of Tasmania, with an area of 26,215 square miles and a population of 227,599, seemed to offer suitable conditions for a study of heredity in ophthalmic disease. Although its population is made up principally of peoples of purely British origin, the investigation, according to Hamilton,¹ was extremely difficult because of the reticence of many residents about their antecedents and because of the sparse and scattered nature of most of the settlements. Of 4,880 patients with eye disease seen by him in private practice during the previous five years 119, or roughly two and one-half in every hundred, proved to have authentically hereditary disease. The diseases observed in these patients, as well as in those seen in hospital practice, represented a variety of conditions and were associated in many instances with a number of hereditary abnormalities of the nervous system, such as amaurotic family idiocy, Friedreich's ataxia and hereditary cerebellar ataxia. The problem, as far as it relates at least to Tasmania, is carefully considered from a number of points of view, including the sociological, educational, employment and welfare aspects. In the prevention of hereditary eye disease, Hamilton's observations that 37.7 per cent of the blind are suffering from hereditary disease of the eye is of great significance. The discussion of this problem follows the outline suggested by Franceschetti at the 1935 meeting of the International Association for the Prevention of Blindness: the collection of precise and complete statistics can be improved by the adoption of a universal form for examination and report on all blind persons admitted to the registry, by a universal definition of blindness, by the certification of the blind only by specially qualified medical practitioners, and finally by the authorization of the collection of accurate statistics by a select subcommittee. In Tasmania as elsewhere, Hamilton points out, Franceschetti's suggestion on the training of physicians in eugenics and the education of authorities and the public has received little support.

1. Hamilton, J. B.: The Significance of Heredity in Ophthalmology: Preliminary Survey of Hereditary Eye Diseases in Tasmania, *Brit. J. Ophth.* 22: 19 (Jan), 83 (Feb.), 129 (March) 1938.

Furthermore, the extension of facilities for premarital consultation with regard to the presence or absence of inheritable disease will incur, Hamilton thinks, the disapproval of the populace, although sooner or later a stand must be taken to combat the evil results of the propagation of hereditary disease. Finally, after brief discussions of the value of increased use of social service workers and decrease in consanguineous marriages, Hamilton reviews the status of hereditary disease of the eye in the light of those countries which have passed sterilization laws and cites the conclusions of the Broche report on the sterilization of the hereditary blind. Certainly, at the very least, an intelligent understanding of such facts as are brought out in studies of this nature is essential.

LOCUS OF DEAMINIZATION

In the course of metabolism, the nitrogen of the absorbed amino acids is removed, converted to urea and largely excreted in this form. In the early years of the present century, feeding experiments showed that alanine was at times converted to lactic acid. The perfusion studies of Embden and Kraus¹ and, later, the striking investigations of Bollman, Mann and Magath² focused attention on the liver as the site where the removal of the amino group from amino acids occurred. As so frequently happens, newer experimental procedures frequently open new vistas with respect to function; for several years the method of surviving tissue slice cultures has been employed to extend the scope of information regarding cellular metabolism. Using this device, Krebs,³ Kisch⁴ and others have demonstrated that, as judged by oxygen uptake and ammonia production when amino acids are added to the nutrient medium, kidney is more active in deamination than is liver. London and his co-workers,⁵ through the use of the angiotomy technic, have called attention to the part played by the intestinal wall in producing ammonia from amino acids. Again, Graham, Houchin and Turner⁶ have shown that the actively secreting mammary gland produces considerable quantities of urea, presumably from the metabolism of amino acids. These newer observations on the biochemical activity of various types of tissue are of fundamental significance; however, as Borsook and Jeffreys⁷ point out, despite the enhanced activity of the kidney, the liver, by virtue of its large relative mass, still is to be considered the most important site of deamination of amino acids. The recent study of Mason,⁸ in which he failed to note any utilization of amino acids by the kidney in unanesthetized dogs, would seem to support the preeminent position of the liver in respect to this phase of the metabolism of amino acids.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Election.—Dr. Charles S. Smith, Nogales, was chosen president elect of the Arizona State Medical Association at its annual meeting in Tucson April 21-23. Dr. Harold W. Rice of Bisbee was installed as president. Other officers are Drs. Leslie R. Kober, Phoenix, vice president; Delamere F. Harbridge, Phoenix, secretary, and Clarence E. Yount, Prescott, treasurer.

CALIFORNIA

Two New Mental Institutes.—Construction will soon begin on two state mental health centers, one in Los Angeles and one near San Francisco, newspapers reported April 10. Authorized by the 1937 legislature, the centers will each cost about \$1,500,000 and have a capacity of 300 beds. All mental cases will be cleared through the centers.

Lectures on Medical Sociology.—The division of medical history and bibliography of the University of California Medical School, San Francisco, recently sponsored a series of open forum meetings on medical sociology. Lecturers and their subjects were:

- Paul Dodd, Ph.D., Cost of Medical Care.
- E. F. Penrose, Ph.D., Theory of Health Insurance.
- E. H. Huntington, Ph.D., Adequate Health Insurance Benefits.
- Dr. Philip K. Brown, Health Insurance in the United States.
- Albert H. Mowbray, A.B., Actuarial Principles of Insurance and Health Insurance.
- Dr. William P. Shepard, The Physician's Place in the Community.
- Dr. Hans A. Meyer, Health Insurance in Germany.
- Dr. John B. de Cusance M. Saunders, Health Insurance in Great Britain.
- Dr. Thomas Henshaw Kelly, Organized Medicine and Health Insurance.
- Dr. Eugene S. Kilgore, Relationship of Government to Medicine.

CONNECTICUT

Lilly Award to Dr. White.—Abraham White, Ph.D., assistant professor of physiologic chemistry, Yale University, New Haven, received the \$1,000 prize and bronze medal of Eli Lilly and Company at the ninety-fifth annual session of the American Chemical Society in Dallas April 18 for his work on sulfur metabolism and protein hormones. Dr. White is a native of Cleveland; he graduated at the University of Denver and later studied at the University of Michigan. He joined the faculty at Yale as instructor in 1933 and became assistant professor last year.

State Medical Meeting at Groton.—The one hundred and forty-sixth annual meeting of the Connecticut State Medical Society will be at the Hotel Griswold, Groton, June 1-2, under the presidency of Dr. Charles H. Turkington, Litchfield. The speakers will include:

- Lieut. Allan S. Chrisman, medical corps, U. S. Navy, Submarine Escape Training.
- Dr. Theodore G. Klumpp, Washington, D. C., chief medical officer, Food and Drug Administration, U. S. Department of Agriculture, Drug Problems.
- Dr. Francis M. Rackemann, Boston, Skin Tests to Foods and Dusts.
- Dr. Roy W. Mohler, Philadelphia, Gonorrhea in Women.
- Dr. Abernethy Benson Cannon, New York, Cutaneous and Systemic Manifestations of Lymphogranuloma Inguinale and Its Differential Diagnosis.
- Dr. Aubrey O. Hampton, Boston, Roentgenological Signs of Bronchial Occlusion, Their Differential Diagnosis and Treatment.
- Charles H. Durfee, Ph.D., Wakefield, R. I., Reeducation of the Problem Drinker.
- Dr. John L. Rice, New York, Syphilis Control in New York City.
- Dr. William Harley Glafke, New York, Changing Attitudes in the Treatment of Peptic Ulcer.
- Dr. Richard Townley Paton, New York, Motion Pictures of Eye Operations.
- Dr. Bernard B. Raginsky, Montreal, Hypnotism and Its Relation to Anesthesia, with Demonstrations.

A symposium on psychiatry and general medicine will be presented by Drs. Charles G. Barnum, Groton, and Eugen Kahn, New Haven, and one on psychiatric service for the community by Drs. Lloyd J. Thompson, New Haven, and Clifford D. Moore, Newtown. Frederic C. Walcott, state commissioner of welfare, will address the annual dinner of the society on "Humane Resources of Connecticut." The Connecticut Association of Medical Examiners and the Connecticut Occupational Therapy Association will also meet. The Hezekiah Beardsley Pediatric Club will be addressed by Dr. Joseph

C. Aub, Boston, on "Endocrine Abnormalities in Childhood." Dr. Eleanor J. T. Calverley, Hartford, will discuss "Medical Experiences in Arabia" at a luncheon of the Women's Medical Society Wednesday morning. The annual meeting of the house of delegates of the state medical society will be held at New Haven May 25, in accordance with a newly adopted plan.

GEORGIA

Personal.—Dr. Abram J. Davis, director of health of Burke County, was elected president of the Southeast Georgia Public Health Association at its meeting April 9 in Waynesboro. Dr. William L. Gilbert, health officer of Fulton County, Atlanta, has resigned on account of ill health but will continue in the position until his successor has been named.

University News.—Crawford W. Long Day was celebrated at the University of Georgia, Athens, March 30. Dr. George A. Traylor, Augusta, president of the Medical Association of Georgia, gave an address. The prize of \$25 offered by the Crawford W. Long Memorial Association to the undergraduate student of the university presenting the best paper on the subject "Why I Wish to Be a Doctor" was awarded to Mr. William Russell, Athens.

Society News.—Dr. John L. Dorough, Monroe, addressed the Walton County Medical Society in Monroe, recently, on "Syphilis as It Relates to Cooks and Other Handlers of Food."—Dr. John R. Martin, Chattanooga, Tenn., discussed "Diagnosis and Treatment of Pathologic Vaginal Bleeding" before a recent meeting of the Catoosa-Dade-Walker Counties Medical Society in Lafayette.—Dr. Otis R. Thompson, Macon, discussed "Human Sterility" before the Macon Medical Society of Bibb County April 5.—At a meeting of the Thomas County Medical Society in Thomasville recently Drs. Benjamin A. Wilkinson, Tallahassee, Fla., spoke on "Pneumonia During Childhood" and Charles H. Ferguson, Thomasville, "Serum Therapy in Pneumonia."

Railroad Surgeons' Meeting.—The eighteenth annual meeting of the Surgical Association of the Atlanta and West Point Railroad Company, the Western Railway of Alabama and the Georgia Railroad was held at the Atlanta-Biltmore Hotel, Atlanta, March 24. Guest speakers included Drs. Oliver C. Wenger, U. S. Public Health Service, on syphilis, and William J. Lancaster, superintendent and medical director, relief department, Atlantic Coast Line Railroad, Wilmington, N. C. Dr. Richard Binion, Milledgeville, delivered the presidential address, on "Surgical Management of Head Injuries."

ILLINOIS

Society News.—The city medical society held a special meeting on syphilis in Peoria April 27; the speakers were Reuben L. Kahn, Sc.D., Ann Arbor, on "Interpreting Paradoxical Serum Reactions in Syphilis"; Dr. Albert E. Russell, Washington, D. C., "Syphilis in Industry," and Dr. David C. Elliott, Springfield, "Syphilis and Its Relation to Public Health." Dr. Herbert R. Edwards, New York, discussed "Tuberculosis Case Finding" before the society May 3 and Dr. Maxim Pollak, Peoria, "Lung Cancer."—Dr. John T. Gernon, Chicago, addressed the McDonough County Medical Society at Macomb April 20 on "Medical and Surgical Consideration of Renal Calculi."—At a meeting of the Will-Grundy County Medical Society April 20 Dr. G. Henry Mundt, Chicago, spoke on "Management of Chronic Nasal Infection."

Chicago

Robber Calls on Pregnant Women.—The Chicago Police Department has reported that a man has been making calls on pregnant women claiming that he was sent by the city or state health department, or some hospital in the vicinity, or the WPA to examine them. He sends the patient in another room to prepare for the examination and then proceeds to rob them of such money or valuables as he can find. The man has so far given no name, he is dark complexioned, about 40 years of age, 5 feet 6 inches tall, weighs about 130 pounds, has gray hair about the temples and wears dark horn-rimmed glasses. He is well dressed, with a blue suit, black oxfords and light gray fedora hat. It is also reported that he has been operating the same racket in Toledo and some other cities. The police department should be notified if this man again makes his appearance.

Research on Psychiatry.—The Rockefeller Foundation has given \$150,000 to the University of Chicago over a period of three years and extended its grant to the Chicago Institute for Psychoanalysis for a period of five years to support research in psychiatry. The gift to the university supplements

the work of a gift of \$168,000 three years ago which financed the establishment of a twelve bed psychiatric unit in the university clinics, staffed by a group of five physicians. Dr. David Sligh, professor of psychiatry, is in charge. In addition to the new grant to the Institute of Psychoanalysis, \$20,000 has been made available for institute fellowships to be awarded young psychiatrists who hold research or teaching posts in psychiatry at universities or other institutions. The institute was founded five years ago with Dr. Franz Alexander as director. The research program has covered the study of emotional factors in the causation of gastrointestinal disturbances, chronic high blood pressure, asthma and hay fever and on the therapy of such cases, the psychoanalytic technic being used.

Rush Alumni Reunion.—The Rush Medical College of the University of Chicago will hold its alumni assembly at the college June 6-7. Clinics covering the specialties will be held at Presbyterian and Cook County hospitals and the Central Free Dispensary, and general discussions will be presented by the following:

Dr. Richard K. Gilchrist, Pathology of Cancer of the Rectum.
Dr. Adrien H. P. E. Verbruggen, Treatment of Acute Brain Injury.
Dr. Ernest E. Irons, Etiology and Pathology of Aspiration Pneumonia.
Dr. George W. Hall, Relationship Between Mental and Surgical Symptoms.
Dr. Gladys R. H. Dick, Scarlet Fever Control.
Dr. William A. Thomas, Water Balance in Medicine and Surgery.
Drs. Willard O. Thompson and Norris J. Heckel, Use and Abuse of Hormone Therapy in Undescended Testicle and Hypogonadism.
Dr. Edward D. Allen, Endometriosis.
Dr. Carl O. Rinder, Hypoglycemia.
Dr. Archibald L. Hoyne, Therapy of Acute Poliomyelitis.
Drs. Arno B. Luckhardt and Jay B. Carter, Ethylene Anesthesia.
Dr. Dean Lewis, Baltimore, Endocrinology of Surgery.
Dr. Albert H. Montgomery, When Not to Operate in Acute Appendicitis.
Dr. Sidney A. Portis, Clinical Significance of Cholecystography.

Dr. Lewis will also address the annual banquet at the Drake Hotel Tuesday evening; Dr. George W. Hall will be the toastmaster.

INDIANA

New Department of Industrial Hygiene.—The state department of public health has created a new department of industrial hygiene with Dr. Louis W. Spolyar, Indianapolis, in charge. Expected to be in operation by July 1, the new department plans as its first activity a general survey of industries of the state and a classification of them as to specific type of employment and the number of persons engaged. Later one health hazardous industry will be selected for detailed study and survey as to the actual amount of industrial disease, according to the state medical journal.

Annual Graduate Course.—The annual graduate course of the Indiana University School of Medicine, Indianapolis, and the Indiana State Medical Association will be held at the medical school May 23-27. The specialties will be covered in clinics, laboratory demonstrations, and clinico-pathologic conferences and the speakers, according to a preliminary program, include Vilhjalmur Stefansson, Ph.D., New York; Drs. Philip C. Jeans, Iowa City; Charles F. McKhann, Boston; Henry G. Poncher, Chicago; James S. Plant, Newark, N. J., and Arthur E. Hertzler, Kansas City. Representatives of the U. S. Army are also scheduled to speak. The county secretaries, state pediatric society and Alpha Omega Alpha will attend special dinners during the session.

IOWA

Annual Renewal Fees Due Before June 1.—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license a licentiate must make a written application to the state department of health before June 1, enclosing the renewal fee of \$1. If a license expires by reason of the licentiate's failure to renew it, it can be reinstated without reexamination only on the recommendation of the state department of health and the payment of the overdue fees.

New Director of Emergency Relief.—Dr. Channing G. Smith, Granger, has been appointed medical director of the Iowa Emergency Relief Administration, succeeding Dr. Thomas C. Denny, Des Moines. Dr. Smith was president of the Iowa State Medical Society in 1931-1932.

KANSAS

Personal.—Dr. Clyde W. Miller has resigned as superintendent of the Sedgwick County Hospital, Wichita, effective May 1.—Dr. Robert C. Hutcheson, Elk Falls, who has been practicing for more than fifty years, was made an honorary member of the Elk County Medical Society at a meeting in Howard March 3.

The Porter Lectureship in Medicine.—The eighth course of lectures under the Porter Lectureship in Medicine was given by Dr. William Boyd, professor of pathology, University of Toronto Faculty of Medicine, Toronto, April 19-20. One lecture was given April 19 on "Bronchial Carcinoma" and two April 20 on "Growth, Normal and Abnormal" and "Nephritis."

MASSACHUSETTS

Course in Medicomilitary Training.—A graduate course for training medical department reserve officers in medicomilitary subjects will be held at the Harvard Medical School, Boston, June 1-14. The course has been planned to afford clinical and didactic graduate instruction in subjects which will be of practical value to medical reserve officers in their daily practice and in training them for emergency duties as army officers. The charges usually made for graduate courses have been omitted by the university and the only payment required will be the regular registration fee of \$5.

State Medical Meeting at Boston.—The one hundred and fifty-seventh annual meeting of the Massachusetts Medical Society will be held at the Hotel Bradford, Boston, May 31-June 2, under the presidency of Dr. Channing Frothingham, Boston. The following will speak, among others:

- Dr. Arthur M. Shipley, Baltimore, Treatment of Peritonitis Complicating Appendicitis.
- Dr. Owen H. Wangenstein, Minneapolis, Acute Bowel Obstruction: Its Recognition and Management.
- Dr. Robert L. DeNormandie, Boston, Cesarean Section in the State of Massachusetts in the Year 1937.
- Dr. John G. Downing, Boston, Are Patch Tests of Real Value in Dermatology?
- Dr. Henry Jackson Jr., Boston, The Protean Character of the Leukemoid States.
- Dr. Thomas H. Lanman, Boston, The Surgical Significance of Urinary Incontinence in Infancy and Childhood.
- Dr. Edward D. Churchill, Boston, The Surgical Treatment of Bronchiectasis.
- Dr. Elliott P. Joslin, Boston, The Diabetic Situation in Massachusetts.
- Dr. James Burns Amberson Jr., New York, The Significance of Latent Forms of Tuberculosis.
- Dr. Frank H. Krusen, Rochester, Minn., Physical Measures of Value to the General Practitioner in the Treatment of Arthritis.
- Dr. Frederick O. Coe, Washington, D. C., The Roentgen Ray Therapy of Inflammatory Lesions.

Dr. Thomas Parran, Washington, D. C., will give an address Tuesday evening on "Work and Aims of the Public Health Service," and Dr. David Riesman, Philadelphia, will deliver the Shattuck Lecture on "America's Contribution to Nosography." The annual oration will be delivered Thursday afternoon by Dr. Allen G. Rice, Springfield, on "The Passing of Surgical Yeomen." A program of entertainment has been planned for the ladies, including luncheon, tea, visits to historic places of interest and a tour of the Isabella Stuart Gardner Museum.

MICHIGAN

School Health Education Institute.—The division of hygiene and public health and the extension service of the University of Michigan, cooperating with the Michigan School Health Association, will conduct a school health education institute May 27-28 at the Michigan Union of the university, Ann Arbor. The speakers will include:

- Dr. John Sundwall, Trends in School Health Education.
- James B. Edmonson, Ph.D., dean, School of Education, University of Michigan, Some Debatable Issues in Health Education.
- Dr. Thurman B. Rice, Indianapolis, Seekers of Health.
- Dr. Henry Cook, Flint, The Medical Profession and the Public Schools.
- Dr. Don W. Gudakunst, Lansing, The State Department of Health and Health Education.
- Dr. Bernard W. Carey, Detroit, The Michigan School Health Association: What It Stands For.
- Dr. John W. Bean, Ann Arbor, The Physiological Basis of Health.
- Dr. Warren E. Forsythe, Ann Arbor, Health Misconceptions.
- Kenneth A. Esslick, D.D.S., Ann Arbor, A Six Point Program for the Improvement of Dental Health.
- Dr. Paul H. Jordan, Ann Arbor, Child Guidance in the Public Schools.

MISSISSIPPI

State Medical Election.—Dr. James P. Wall, Jackson, was chosen president elect of the Mississippi State Medical Association at its annual meeting in Jackson April 21 and Dr. Joseph E. Green, Laurel, was installed as president. Other officers chosen were vice presidents: Northern district, Dr. Monteville Q. Ewing, Amory; central district, Dr. Richard B. Austin, Forest, and southern district, Dr. Benjamin T. Robinson, New Augusta. The next annual session will be held in Gulfport. A resolution was approved establishing a fund for indigent and disabled physicians.

NEW MEXICO

State Medical Meeting in Santa Fe.—The fifty-sixth annual meeting of the New Mexico Medical Society will be held at La Fonda Hotel, Santa Fe, June 6-8, under the presidency of Dr. Eugene W. Fiske, Santa Fe. Guest speakers announced are:

- Dr. Felix P. Miller, El Paso, Texas, Prevention of Accidents.
- Dr. Francis C. Goodwin, El Paso, Complicated Fractures.
- Dr. James J. Gorman, El Paso, Jaundice: Its Significance as a Symptom.
- Dr. Henry T. Safford, El Paso, Anal Infections.
- Dr. Horton R. Casparis, Nashville, Tenn., Nutrition in Infants and Children.
- Dr. Gerrit Heusinkveld, Denver, Subinvolution of the Uterus.
- Dr. Verne C. Hunt, Los Angeles, Lateral Gastroduodenostomy in the Surgical Treatment of Duodenal Ulcer.
- Dr. Harold C. Habein, Rochester, Minn., Intravenous Medication.
- Dr. Gottlieb Werley, El Paso, Angina, Atherosclerosis and Food Allergy.
- Dr. Thomas E. Carmody, Denver, Present Status of Treatment of Sinus Disease.
- Dr. Arthur E. Smith, Los Angeles, Reconstructive and Plastic Surgery.
- Dr. Arthur Elmer Belt, Los Angeles, Endocrinology of Prostatic Hypertrophy.
- Dr. Frank R. Teachenor, Kansas City, Mo., Surgical Treatment of Cranial-Cerebral Injuries.

New Mexico physicians on the program are Drs. John R. Van Atta, Albuquerque, on "Short Wave Therapy"; Donat F. Monaco, Gallup, "Management of Intestinal Obstruction," and Lee M. Miles, Albuquerque, "Ectopic Pregnancy."

NEW YORK

New Home for Rochester Societies.—The Rochester Academy of Medicine recently raised a fund of \$150,000 to enlarge its headquarters and to establish an endowment fund. The academy has received also as a gift the home of the late Edmund Lyon, philanthropist, presented by his daughters as a memorial to their parents. The home is a brick house on East Avenue, with thirty-two rooms and four acres of landscaped grounds. The first floor will be used as a lounge, the

New home of Rochester medical societies.

second will be remodeled for the academy's library and the third has an auditorium, which will be retained for small meetings. An addition will be built beside the old building providing an auditorium for 400 persons and a stackroom to open into the library room. The Medical Society of the County of Monroe and the Rochester Pathological Society will share the building with the academy. This will be the third home of the academy. The first was purchased in 1914 near the business district of the city and sold ten years later. The present home near the women's college of the University of Rochester has become inadequate. Dr. Albert D. Kaiser, president of the academy during the past year, is chairman of the building project. Dr. David B. Jewett, chairman of the library committee, is president for the coming year.

New York City

British Medal to Dr. Schick.—The Addingham Gold Medal has been awarded by the University of Leeds, England, to Dr. Bela Schick, chief of the pediatrics department of Mount Sinai Hospital, in recognition of his development of the susceptibility test for diphtheria and other contributions to medicine. The medal was presented in absentia April 12 by the Lord Mayor of Leeds. Dr. Schick received the gold medal of the New York Academy of Medicine March 3 on the twenty-fifth anniversary of the announcement of the Schick test (THE JOURNAL, March 19, p. 906).

Dr. Goldwater Retires from Public Service.—Dr. Sigismund S. Goldwater, since 1934 commissioner, department of hospitals, New York City, has announced his retirement, but will continue in office until the appointment of his successor, according to the *New York Times*. Dr. Goldwater was superintendent of Mount Sinai Hospital from 1903 to 1916 and director from 1917 to 1929. He was commissioner of health of New York City from 1914 to 1918, and, in 1908, municipal expert in hospital construction and administration of New York. In 1908 he was president of the American Hospital Association, in 1913 vice president of the New York Academy of Medicine, in 1918-1921 vice president of the National Institute of Social Sciences and from 1924 to 1926 president of the American Conference on Hospital Service. He was medical counselor of the U. S. Veterans' Bureau in 1924. He is 65 years of age.

OHIO

Hospital News.—A new building was recently dedicated for the Toledo Convalescent Home for Crippled Children. It has facilities for eighty-eight children and cost \$250,000. It is under the sponsorship of the Toledo Society for Crippled Children.

Lectureship Endowed.—Dr. William E. Lower, Cleveland, has given to the Academy of Medicine of Cleveland a fund to be used for a lectureship of general interest to the medical profession. Dr. Lower directed that the lecture deal with some recent development or research, if advisable, but not confined exclusively to any one branch of medicine.

Society News.—Dr. Frederick A. Collier, Ann Arbor, will discuss "Water Balance in Surgical Patients" before the Academy of Medicine of Cincinnati May 24.—Dr. Claude S. Beck, Cleveland, addressed the annual meeting of the Cleveland Academy of Medicine May 20 on "Surgery of the Heart."—Dr. George I. Bauman, Cleveland, addressed the Summit County Medical Society, Akron, May 3 on osteomyelitis.—At a meeting of the Marion Academy of Medicine March 1 Dr. Karl D. Figley, Toledo, spoke on "Management of Pollen Therapy in Hay Fever and Asthma."—Dr. John A. Fraser, East Liverpool, addressed the Columbiana County Medical Society, Lisbon, March 8 on "Analgesia and Anesthesia in Obstetrics."—Dr. Daniel G. Sanor Jr., Columbus, addressed the Guernsey County Medical Society, Cambridge, March 3 on "Pathology of the Eye."—Dr. Harold G. Reineke, Cincinnati, addressed the Montgomery County Medical Society, Dayton, April 1 on "X-Ray Studies on Differential Diagnosis of Tuberculosis."—Dr. Charles E. Galloway, Evanston, Ill., addressed the Toledo Academy of Medicine, April 1, on "Lesions of the Cervix."

PENNSYLVANIA

Society News.—Dr. Samuel G. Henderson, Vandergrift, among others, addressed the Westmoreland County Medical Society, Scottdale, April 26, on "X-Ray Therapy in Carcinoma of the Breast."—Dr. Lester Hollander, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, May 5 on cancer and conducted a clinic on skin disease.

Annual Clinic.—The Westmoreland County Medical Society will conduct its annual clinic in New Kensington May 26. The speakers will be:

Dr. George P. Muller, professor of surgery, Jefferson Medical College, Philadelphia.
Dr. Clifford B. Lull, assistant professor of obstetrics at Jefferson.
Dr. Edward L. Bortz, associate professor of medicine, University of Pennsylvania Graduate School of Medicine.

C. William Duncan, columnist, *Philadelphia Evening Ledger*, will be the guest speaker at the dinner.

District Meeting.—The Seventh Councilor District Medical Society held its annual meeting at the Williamsport Country Club, Williamsport, May 13. Addresses were delivered by the following officers of the state medical society: Drs. Walter F. Donaldson, Pittsburgh, secretary; Frederick J. Bishop, Scranton, president, and David W. Thomas, Lock Haven, president-elect. Fifty year testimonials were presented to the following:

Dr. Reuben H. Born, Montoursville, fifty-one years in practice.
Dr. Solomon F. Hakes, Tioga, fifty years in practice.
Dr. Wesley F. Kunkle, Williamsport, fifty years in practice.
Dr. Henry H. Smith, Johnsonburg, fifty-one years in practice.

Dr. Arthur C. Christie, Washington, D. C., discussed "Social Trends in Medicine." The woman's auxiliary held its annual meeting the same day.

RHODE ISLAND

State Medical Meeting.—The one hundred and twenty-seventh annual meeting of the Rhode Island Medical Society will be held at the Rhode Island Medical Library, Providence, June 1-2, under the presidency of Dr. Walter C. Rocheleau, Woonsocket. Clinics will be held at the local hospitals. Included on the program are the following out of state speakers:

Dr. Robert M. Zollinger, Boston, Surgical Aspects of Peptic Ulcer.
Dr. William C. Quinby, Boston, Clinical Aspects of Testicular Tumors.
Dr. Varaztad H. Kazanjian, Boston, First Aid Treatment of Injuries of the Face and Jaws.
Dr. Herbert M. Elder, Montreal, Diagnosis and Treatment of Peripheral Vascular Disease.
Dr. Israel M. Rabinowitch, Montreal, Diabetic Coma.
Dr. Alvah H. Gordon, Montreal, Diagnosis of Diseases with Coincident Enlargement of the Liver and Spleen.
Dr. Richard M. Smith, Boston, Do We Consider the Child as a Whole?
Cleophas P. Bonin, D.M.D., Boston, Pediatric Significance of Malocclusion.
Dr. John R. Richardson, Boston, Nasal Airways.
Dr. Clarence E. Bird, Louisville, Ky., Physiology, Pathology and Treatment of Diseases of the Esophagus.

The annual dinner will be addressed by Samuel T. Arnold, Ph.D., dean of Brown University, and John C. Cosseboom.

SOUTH CAROLINA

Historical Commission Appointed.—A commission has been organized in South Carolina to gather, preserve and publish when possible material on the history of the South Carolina Medical Association. Members are Drs. Robert E. Seibels, Columbia; Hillyer Rudisill Jr., Charleston; Linnaeus C. Shecut, Orangeburg; Daniel Lesene Smith, Spartanburg, and Joseph I. Waring, Charleston, who is chairman. The appointment of the commission was approved at the annual meeting of the state association in 1937.

Public Health Meeting.—The South Carolina Public Health Association will hold its annual meeting at Myrtle Beach May 23-25, with headquarters at the Seaside Inn and conferences at the Gloria Theater. Dr. William K. Fishburne, health officer of Berkeley County, Moncks Corner, is president. The out of state speakers include Drs. Arthur T. McCormack, Louisville, Ky., Knox E. Miller, senior surgeon, U. S. Public Health Service, John A. Ferrell of the International Health Division, Rockefeller Foundation, New York, and Milton J. Rosenau, Chapel Hill, N. C. Other speakers will include:

Dr. William Weston Sr., Columbia, Food as a Public Health Factor.
Dr. William Atmar Smith, Charleston, The Public Health Aspect of Collapse Therapy in Tuberculosis.
Dr. Edgar A. Hines, Seneca, The Trend of Public Health Activities in Pediatric Practice.
Dr. Robert Wilson, dean, Medical College of the State of South Carolina, Charleston, General Practice and Its Relation to Public Health.

TENNESSEE

Medicomilitary Training Course.—Vanderbilt University School of Medicine, Nashville, will conduct a medicomilitary inactive duty training course for medical reserve officers of the U. S. Army and Navy in conjunction with its commencement clinic, June 6-7. The course will combine graduate work with a conference on medicomilitary problems. Enrollment is open to all reserve officers of the medical department of the army and navy and to medical officers of the National Guard.

UTAH

Personal.—Dr. Wendell Noall has been appointed health officer of Ogden, succeeding Dr. Wilburn J. Wilson.

Society News.—Dr. Ray T. Woolsey, Salt Lake City, addressed the Central Utah Medical Society at Salina April 6 on "Obstetrical Problems and the Cesarean Section."—At a meeting of the Weber County Medical Society recently Dr. June P. McBride discussed diseases of the retina and Howard K. Belnap, Ogden, cryptitis and its relation to fissure rectal abscess, fistula rectal abscess and fistula formation.

WISCONSIN

Dr. Harper Honored.—Dr. Cornelius A. Harper, Madison, has completed thirty-four years as state health officer, making him the senior public health official in the United States in point of unbroken service. A testimonial dinner was held in his honor April 1 by his department personnel and on April 10 he with others was honored at the Conference of State and Provincial Health Authorities of North America for having completed more than twenty-five years in public service. A native of Wisconsin, Dr. Harper graduated in medicine at Columbian University, now George Washington University School of Medicine, Washington, D. C., in 1893. He was appointed to the state board of health in 1902 and became

administrative head in 1904. He was president of the State and Provincial Health Officers of North America in 1908 and of the Wisconsin State Medical Society in 1930. He was a member of the state legislature in 1911.

Society News.—Dr. Raymond W. McNealy, Chicago, was the guest speaker before the Medical Society of Milwaukee County April 8 on "Medical and Surgical Treatment of Duodenal Ulcer."—Drs. Samuel Wick and Herbert J. Apfelberg, Wauwatosa, addressed the Milwaukee Neuro-Psychiatric Society March 24 on "Treatment of Schizophrenia with Insulin and Metrazol" and "Korsakoff's Psychosis" respectively.—Drs. Henry A. Sincock and Charles W. Giesen, Superior, addressed the Barron-Washburn-Sawyer-Burnett Counties Medical Society in March on "Prevention of Disease in Children Under One Year of Age" and "Diagnosis and Treatment of Common Skin Diseases" respectively.

GENERAL

Society News.—The American Association of Medical Social Workers will hold its national conference in Seattle, June 26-July 2.—Dr. Jon N. Kelly, La Porte, Ind., was elected president of the Northern Tri-State Medical Association at its annual meeting in Findlay, Ohio, April 12. Dr. Robert H. Elrod, Toledo, Ohio, was made vice president and Donald R. Brasie, Flint, Mich., secretary. Next year's meeting will be in South Bend, Ind.

Officers of Biological Societies.—At the annual meeting of the Federation of American Societies for Experimental Biology in Baltimore March 30-April 2, officers of the societies were elected as follows:

American Society of Biological Chemists: Glenn E. Cullen, Ph.D., Cincinnati, president, and Charles G. King, Ph.D., Pittsburgh, secretary.
American Physiological Society: Dr. Walter E. Garrey, Nashville, Tenn., president, and Dr. Andrew C. Ivy, Chicago, secretary.
American Society for Pharmacology and Experimental Therapeutics: Dr. Arthur L. Tatum, Madison, Wis., president, and Dr. Gustave Philip Grabfield, Boston, secretary.
American Society for Experimental Pathology: Dr. Charles Phillip Miller, Chicago, president, and Dr. Paul R. Cannon, Chicago, secretary.

The next meeting will be in Toronto, Canada, in March 1939.

Examinations in Obstetrics and Gynecology.—The oral, clinical and pathologic examinations for group A and group B applicants will be held by the American Board of Obstetrics and Gynecology in San Francisco June 13-14. An informal dinner for diplomates will be held Wednesday evening June 15 at the Palace Hotel, with Dr. William D. Cutter, secretary of the Council on Medical Education and Hospitals of the American Medical Association, Chicago, as the speaker. Tickets at \$2.25 each may be obtained in advance from Dr. Joseph L. Baer, 104 South Michigan Avenue, Chicago, or at the door. Application blanks and other information may be obtained from Dr. Paul Titus, secretary of the board, 1015 Highland Avenue, Pittsburgh.

Meeting on Industrial Medicine.—The twenty-third annual meeting of the American Association of Industrial Physicians and Surgeons and the second annual Midwest Conference on Occupational Diseases will be held at the Palmer House June 6-9. The following, among others, will speak:

J. J. Bloomfield, P. A. sanitary engineer, and Richard T. Page, associate public health engineer, division of industrial hygiene, U. S. Public Health Service, Washington, D. C., Estimation of Potential Health Hazards and Their Control.
Wallace Waterfall, director of research engineering, the Celotex Corporation, Chicago, Noise in Industry.
Oliver G. Browne, general claims attorney, New York Central System, New York, Developments in Occupational Disease Legislation.
Voyta Wrabetz, chairman, Industrial Commission of Wisconsin, Madison, Wis., The Employability of the Silicotic.
Dr. Hart E. Fisher, medical director, Chicago Rapid Transit, Chicago, Hazards of Night Driving.

The Chicago Regional Fracture Committee, American College of Surgeons, will present a symposium Thursday afternoon, with the following speakers:

Dr. Kellogg Speed, Chicago, Fractures of the Carpal Navicular Bone.
Dr. Paul B. Magnuson, Chicago, Prevention versus Cure in Deformity Following Fracture.
Dr. Dean L. Rider, Riverside, Ill., March Foot.
Dr. Willis J. Potts, Oak Park, Ill., Treatment of Fractures of the Neck of the Femur by Pinning.
Dr. Hugh McKenna, Chicago, Treatment of Fractures of the Neck of the Femur.

Boston Wins in Health Conservation Contest.—The Chamber of Commerce of the United States in cooperation with the American Public Health Association has designated Boston as the winner in the city health conservation contest among cities with a population of more than 500,000. Additional awards in this group went to Cleveland and Pittsburgh. There were 263 entries in the 1937 contest and the awards are given to those cities which, in the opinion of a committee of health experts, have during the past year dealt most effectively

with their local health problems. Activities considered in judging the contest include safety of water supply, satisfactory sewage disposal, adequate supervision of milk supply, planned medical and nursing service for mothers and infants, and safeguarding the community by recognized preventive measures, with special emphasis on school health and control of tuberculosis and venereal disease.

Announce Establishment of New Board of Anesthesiology.—The American Board of Anesthesiology has been organized as an affiliate of the American Board of Surgery in response to many requests to establish official recognition of physicians competent to practice and teach anesthesiology as a specialty. The affiliation was approved by the Advisory Board for Medical Specialties in February 1938. Cooperating societies include the Section on Surgery of the American Medical Association, American Society of Anesthetists, Inc., and the American Society of Regional Anesthesia, Inc. The term of membership on the new board will be six years. Present members are Drs. Thomas Drysdale Buchanan, New York, president; Henry S. Ruth, Philadelphia, vice president; Paul M. Wood, New York, secretary-treasurer; John S. Lundy, Rochester, Minn.; Emery A. Rovenstine, New York; Harry Boyd Stewart, Tulsa, Okla.; Ralph M. Tovell, Hartford, Conn.; Ralph M. Waters, Madison, and Philip D. Woodbridge, Boston. Two groups of candidates are recognized for qualification by the board: those who have already amply demonstrated their fitness as trained specialists in anesthesiology, the Founders' Group, and those who, having met the general and special requirements exacted by the board successfully pass its qualifying examination. The Founders' Group, on invitation by the board, may be chosen from (1) professors and associate professors of anesthesia in approved medical schools in the United States and Canada, (2) those who for fifteen years prior to the board's organization have limited their practice to anesthesiology, and (3) those who hold the certificate of fellowship in the American Society of Anesthetists, Inc. All applications for the Founders' Group must be received by Jan. 1, 1939. No candidate will be considered after that date. Requirements for those to be qualified by examination will be: 1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association or graduation from an approved foreign school. 2. Completion of an internship of not less than one year in a hospital approved by the Council or its equivalent in the opinion of the board. 3. Special training: A further period of graduate work of not less than three years devoted to anesthesiology taken in a recognized graduate school of medicine or in a hospital or under the sponsorship accredited by the American Board of Anesthesiology for the training of anesthetists. The period of training shall be of such character that the relation of the basic sciences to anesthesiology shall be emphasized. Adequate clinical experience in which the candidate has assumed the whole responsibility will be required. An additional period of not less than three years of study or practice limited to anesthesiology. 4. The candidate must present to the board sufficient evidence of good moral character and that he has limited his practice to anesthesiology as a specialty and that he intends to be so engaged.

The qualifying examination will be divided into two parts: Part I will consist of a written examination covering such topics as anatomy, biochemistry, physiology, pharmacology, physical diagnosis, therapeutics, pathology and public health, in relation to anesthesiology. Part II, oral and practical, may cover similar topics, and, in addition, such questions on physics and mechanics as are important in anesthesiology, especially dealing with electrical theories and the proper handling of high pressure gases and inflammable agents. The practical examination will consist of actual observation of clinical work in the applicant's own operating theater when possible, and it may consist of cadaver demonstrations of regional blocks, sites for alcohol injection, and procedures for resuscitation or inhalation therapy and clinical experimentation.

The fee for Group A, Founders' Group, shall be \$25. The fee for Group B shall be \$50, payable \$25 on application, which shall be returned if the candidate is not accepted for examination, and \$25 on taking the examination. Reexamination within two years may be had if necessary without additional fee. Once a candidate has become qualified he will have no further financial obligation to the board.

The board postponed its first examination (part I, written), which was scheduled for July 1938. Part I and part II will be held in New York City October 21. Requests for booklets of information and application blanks should be addressed to the secretary, Dr. Paul M. Wood, 745 Fifth Avenue, New York.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 23, 1938.

A General Medical Service for the Nation

The present national health insurance applies only to employed persons and is compulsory for all whose income is below \$1,250. It does not apply to the dependents of the employed or to workers of similar social standing who are not employed by any one. The council of the British Medical Association has brought forward a scheme for extending health insurance to the whole population. "There should," it says, "be provided for every individual the services of a general practitioner or family doctor." Though so worded it is probably not meant that every person should be compelled to join but only, as at present, those below a certain income level. The effect would be to double the number of the insured. The present system provides only a general practitioner service as a matter of course, though there are other medical benefits, which are contingent. As to how the scheme is to be financed, nothing is said. The present scheme is financed jointly by contributions from employers, the employed and the state. The council states that there exists a plethora of health services, better than those in any other country, but established in piecemeal more or less haphazard fashion, with consequent overlapping and unnecessary complication and also large gaps. Locally there are now two systems of medical provision, one under the insurance committees, the other under the local authorities, which are largely independent. The former provide a general practitioner service for 19,000,000 persons. The latter provide an environmental health service, a general practitioner service for the destitute, a school medical service, a maternity service based mainly on attendance by midwives, supervision of mental defectives, clinics for infant welfare, early mental disorders, venereal diseases and tuberculosis, consultants and specialists for certain purposes, and general and special hospitals. In addition certain voluntary bodies, such as those concerned with infant welfare and public health, render service.

The council considers that any general medical service for the nation should include, in addition to the environmental health and sanitary service, a general practitioner service, nursing, massage and physical medicine, dental and ophthalmic services, a maternity service, a consultant, specialist and laboratory service, and an institutional service. The council proposes that the existing insurance system shall be extended to the dependents of the present insured, those receiving domiciliary medical attendance through public assistance machinery, and others of similar economic status to the present insured though not under a "contract service." In association with the general practitioner service should be provided certain auxiliary services of lay persons, such as pharmacists, nurses, masseuses and biophysical assistants. Similarly there would be dental and ophthalmic benefits for all the insured and not, as now, "additional benefits" for some. Under the existing scheme all insured persons have a general practitioner service and a cash benefit in respect to maternity. Many, but not all, the insured have additional treatment benefits, depending on the funds of their societies. These are payments in respect to dental and ophthalmic treatment, convalescent home treatment, medical and surgical appliances and, to a much smaller extent, hospital accommodation. In the view of the medical profession, full dental and ophthalmic benefit should be provided as part of the insurance service. Specialist services in tuberculosis, in venereal and infectious diseases and in laboratory examinations are already provided by local authorities. It is proposed that

the consultant and specialist service should be comprehensive in all branches and should be available only through the general practitioner.

The maternity service should include (1) antepartum care by or under the responsibility of a medical practitioner chosen by the patient, throughout pregnancy; (2) attendance by a certified midwife during the antepartum period, labor and the puerperal period; (3) attendance by the practitioner when necessary; (4) at least one postpartum consultation with the practitioner; (5) a second practitioner when necessary, as for administration of an anesthetic; (6) a consultant when necessary; (7) a laboratory service; (8) beds for persons requiring institutional treatment; (9) sterilized obstetric dressings; (10) ambulance facilities for patients requiring removal to institutions, and (11) women trained in domestic work, who would relieve the mother during the lying-in period.

The Spread of Streptococcic Infection as Ascertained by Type Determination

At the Society of Medical Officers of Health a discussion on infections was introduced by Dr. V. D. Allison of the Ministry of Health Pathological Laboratory. The main value of type determination in infections due to *Streptococcus pyogenes* was in (1) investigating the sources and paths of infection in explosive outbreaks of streptococcic infection, such as those due to milk, and outbreaks of puerperal fever in maternity hospitals, and (2) investigating the paths of infection in the wards of general and fever hospitals, and the effects of reinfection and cross infection in producing grave complications.

His investigations in scarlet fever wards had shown the following: 1. Patients nursed throughout their illness in cubicles or chambers show no change of the serologic type of the infecting streptococcus. Segregation of patients in small wards according to the serologic type of the infecting streptococcus showed that if a change of type did occur it was due to introduction of fresh infection by a member of the staff. 2. Infection with one serologic type of *Str. pyogenes* does not necessarily protect a patient against infection with another type. 3. The so-called relapse in scarlet fever is due to fresh infection with a streptococcus conveyed by another patient in the ward and differing in serologic type from that causing the primary infection. 4. In multiple bed wards for scarlet fever from 50 to 70 per cent of the patients become reinfected with one or more fresh types of *Str. pyogenes* during their stay in the hospital. 5. Such reinfection may be latent or manifest. 6. Complications in scarlet fever during the third week and subsequently in multiple bed wards are usually caused by reinfecting types of *Str. pyogenes*.

Dr. Allison gave experimental proofs of spread of infection by direct and indirect contact and pointed out the importance of infected toys, handkerchiefs and eating utensils as vehicles of infection. Air-borne infection by droplets was well recognized, but the part played by particles of dust, in which *Str. pyogenes* could survive for a considerable time, was only beginning to be recognized. The problem of the spread of streptococcic infection was of equal importance in measles wards and in the wards of general hospitals.

Dr. R. Cruickshank referred to air-borne infection (not droplet or spray infection). Recent epidemiologic and bacteriologic work suggested that infection—and not only respiratory tract infection—was spread in spite of rigid precautions to prevent transference manually by fomites or by carriers. Droplets did not always fall immediately to the ground within a few feet of the individual. If not more than 0.1 mm. in diameter, evaporation rapidly reduced them to such a small size that they remained suspended in the air like particles of smoke. Larger droplets which had settled might also evaporate and be lifted into the air again as dust. Wells showed that certain organisms which commonly occurred in the upper respira-

tory tract—hemolytic streptococci, pneumococci and diphtheria bacilli—remained viable in the atmosphere for two days. Dr. Cruickshank found that in eight cases of burns in a ward infection with the same type of *Str. pyogenes*, which he cultivated from the dust, was present. In a small outbreak of puerperal sepsis he found *Str. pyogenes* in the atmosphere of the ward. In a diphtheria ward of young children streptococcal infections (tonsillitis, otitis media and vaginitis) occurred. Streptococci of the two infecting types were found on plates exposed in the ward and were more numerous where the infected patients were.

Fatal Case of Psittacosis at the Zoological Gardens

After an absence of psittacosis from this country for some years a case has occurred at the London Zoological Gardens. An attendant, aged 41, died from the disease, which he contracted in the course of his employment. At the inquest it was stated that he was supposed to be suffering from typhoid, but by injecting material from some of the organs into mice Prof. S. P. Bedson produced psittacosis in them. Mr. D. S. Smith, curator of birds and mammals at the Zoological Gardens, said that this was the first case in their more than one hundred years' history. It originated in a consignment of parrots brought from South America and the West Indies by Lord Moyne. As was customary, the birds were all kept in the sanatorium for a week or two. They had never been on exhibition to the public, and the whole consignment was destroyed as a precaution. The jury added to their verdict the statement that they were satisfied that every precaution had been taken by the authorities of the Zoological Gardens.

Complicated Tax System for French Physicians

Every physician and dentist in France is obliged to pay an income tax, a personal property tax and a third type of tax known as the "patente" or license to practice. A physician or dentist must keep a separate ledger in which the name of each patient and the amount paid for services are recorded daily. Instead of inscribing the name of the patient, a number may be given and the fee received placed opposite the number. The tax collector has the right, if there is any question as to the net annual income, after the usual deductions for professional expenses, to inspect the record of how much was received from each patient. Such a request for inspection of the daily receipts is rarely made, but the physician or dentist who does not keep such a ledger is liable to a heavy fine.

The "patente" or license tax is based on the rental value of the space occupied for professional purposes. If the office is in the physician's or dentist's apartment, used also as living quarters, the "patente" is calculated on the rental value of such rooms as are used in the practice of medicine or dentistry. Up to a few years ago, the "patente" was levied not only on the offices used by a physician or dentist in a city like Paris but also on the rental value of any suburban or country residence. Fortunately, this double, or triple in some cases, mode of collecting the "patente" has been abolished. However, recently the question was raised as to whether a physician who spends his vacation in some country town and receives fees for services rendered during his sojourn there is liable for the payment of an additional "patente." The minister of finance, in reply to such a question, raised in parliament on January 11, replied in the affirmative: The "patente" must be paid for such vacation receipts unless the services rendered are not reimbursed.

This "patente" or annual license to practice tax constitutes in many cases a heavy additional burden which is keenly felt

in the present state of crisis here. Not only the medical and dental professions, but all "noncommercial pursuits," such as architects, engineers and accountants, must pay the "patente" tax.

Bacillus Funduliformis Infections

A number of articles have appeared in recent years in which cases of septicemia due to *B. funduliformis* were reported. This organism is strictly anaerobic and difficult to grow on mediums. At the March 29 meeting of the Académie de médecine of Paris, attention was called to the surgical aspects of *B. funduliformis* by Lemierre, Grégoire and their co-workers. The organism is constantly found in the normal digestive and urinary tracts and is apt to give rise to suppuration when perforation of the various components of these tracts occurs. The majority of reports of infection due to this organism are those of cases of tonsillitis and peritonsillar abscess and of otitis and mastoiditis. It is important for surgeons to be cognizant of the existence of bacteremias caused by *B. funduliformis*. In the clinical picture, the triad of symptoms (a) severe and prolonged chills followed by high temperatures, (b) pulmonary infarcts complicated by empyema and (c) arthritis, often suppurative, dominates.

To prevent spread of the infection from the most frequent primary foci in the pharynx and ear, attempts have been made to ligate the internal jugular vein, but this has not been successful in most cases.

An empyema which is a sequel of a generalized *B. funduliformis* infection should be operated on as soon as possible after the diagnosis of such a complication has been made. The *B. funduliformis* empyema shows a tendency to rupture into the bronchi and is often the only clinically demonstrable localization of the bacteremia. The metastatic osteo-articular foci also call for early intervention because of a similar tendency to perforate the joint capsule and invade the periarticular tissues. In one case, even though arthrotomy was performed on one shoulder and two elbow joints, the patient died. In another patient a suppurative arthritis had perforated the acetabulum and invaded the pelvic tissues. In spite of good drainage this patient died. In both of these cases, a large number of septic infarcts were found in the lungs at necropsy. Localization of the infection in the sacro-iliac joint is common. The termination in these cases of *B. funduliformis* bacteremia is not always fatal. The clinical course may be short without any localization calling for surgical intervention, or the latter may result in recovery, as in some cases in which an early diagnosis of such a localization has been made.

Lesions of Ulnar Nerve in Supracondyloid Fractures

At the March 16 meeting of the Académie de chirurgie of Paris, a paper was read by Prof. E. Sorrel and Dr. Sorrel-Déjerine in which twenty-one instances of injury to nerves following fracture of the lower end of the humerus were reported. In fifteen cases the ulnar nerve was involved; in one, the radial and in two, the median. Seven of the first named complicated a transverse supracondyloid fracture of the humerus. Such paralyses are relatively rare, according to the literature. The authors' seven cases occurred in a total of 207 transverse supracondyloid fractures, so that the incidence of paralysis of the ulnar nerve may be considered to be about 7 per cent.

Among these 207 cases, injury of the ulnar nerve was never observed in 184 of the type termed "extension fractures" by Kocher. In this type, the lower fragment is displaced behind the shaft, whereas in the "flexion" type the lower fragment is displaced in front of the shaft of the humerus. All seven cases of ulnar paralysis occurred in this second or flexion type.

of fracture, so that the incidence is 30 per cent, the nerve being caught between the two fragments, the epiphysis and the shaft.

The symptoms of paralysis of the ulnar nerve are not very evident during the first few days after the injury. Often the paralysis is an incomplete one, the entire nerve not being involved. In only two of the seven cases reported by the authors was paralysis complete. It is important to make an early diagnosis of a nerve injury; hence the signs of such an involvement should be looked for in all supracondyloid fractures of the humerus in children. In three cases, injury to the nerve was recognized only following removal of the cast. Aside from the evidence of motor and sensory paralysis, vasomotor disturbances, such as marked dryness of the skin, are important objective signs. If the nerve injury is recognized early, the prospect of complete recovery is good. In one case, the nerve was found crushed between two fragments at the time of operation two days after the injury; nevertheless complete recovery was noted seven months later. In another child, the nerve was not found crushed but simply stretched over a fragment four months after the injury. Recovery following operation took place in much shorter time (three weeks) than in the preceding case.

If evidences of compression of the ulnar nerve are present but a good nonoperative reduction has been effected, it is safe to wait two weeks, but no longer, before operating, to see whether reduction of the fracture has succeeded in releasing compression of the nerve. If, however, the reduction is unsatisfactory, it is advisable to operate immediately.

Dedication of Monument in Memory of Professor Calmette

The city in which the late Professor Calmette was born has honored his memory by the erection of a monument, which was unveiled at Nice, April 8. The work depicts a nurse administering the BCG vaccine to an infant, which she holds in her arms. On the side of the monument is a plaque of the distinguished bacteriologist, who during the last years of his activity at the Pasteur Institute of Paris devoted his energies to the prevention of tuberculosis in the newborn by means of the BCG vaccine.

The Survival of Prematurely Born Infants

"Prematurely born" is the term applied to infants whose weight at birth is less than 2,500 Gm. It has been deemed necessary to determine whether survivors of this group would grow up to be burdens on their families and on society. Professor de Rudder, ordinarius in pediatrics at Frankfurt, undertook to solve this problem. Since evaluation also of mental development is of prime importance, children of school age were selected for investigation. That his material would be representative, the author limited his choice to children whose weights at birth had been from 1,000 to 1,700 Gm. This weight level approximates from one third to one half the neonatal weight of a baby born at term.

De Rudder established that the mortality among "tiny prematures," babies whose weight at birth is 1,700 Gm. or less, during the first months of life was extremely high despite the best of hospital care. Some 75 per cent of these babies die of general debility, injuries received during births, and so on. The author was able to make follow-up examinations of twenty-seven children from 6 to 17 years of age who had been "tiny prematures." Nearly all these children had spent their earliest infancy in the Frankfurt Children's Hospital; consequently, precise data relative to that period were available. He found that the physical development of these children with respect

to height and weight corresponded completely with the norm for their respective ages. This conformity has been noted by other investigators. In no instance was any defect such as a crippled condition of any sort or spasmophilia observed which could be referred to premature birth. Evaluation of mental development was based on various criteria: social environment, data supplied by relatives, impressions conveyed during medical examination, intelligence tests, and direct questioning of the teachers. Of the twenty-seven children only one was manifestly feeble-minded and four attended special schools for backward children. The remaining twenty-two children attended regular school and were rated as average and in some instances as superior pupils. Rather deficient powers of concentration, inattention and slight mental fatigability were a few peculiarities repeatedly evidenced by these children. The prognosis for the children investigated is favorable and the question as to the survival value of "tiny prematures" can without reservation be answered in the affirmative.

AUSTRALIA

(From Our Regular Correspondent)

March 29, 1938.

Infant Mortality in South Australia

The statistical register of the state of South Australia for 1936-1937 shows that although the 589,000 inhabitants enjoy good health, judging by their death rate and longevity, and although in 1936 their infant mortality rate was equal to the lowest in the world, their birth rate is consistently the lowest of the Australian states and in 1936 was only 15 per thousand. South Australia has the lowest death rate in the commonwealth (a standardized rate of less than 8 per thousand), an expectation of life at birth of 65 years, and an infant mortality rate of 31 deaths per thousand live births. In 1915, 117,409 women of child bearing ages produced nearly 12,000 children; in 1935, 156,940 women gave birth to a little more than 8,000. The result is that at the census of 1933 there were 8,762 less children under 5 years of age than there were at the census taken twelve years earlier, and in the latest year the population has increased by less than 3,000. This is an odd position for a young country and a discouraging outlook. The low fertility, but not the low mortality, may be explained by the fact that rather more than half the population lives in and around Adelaide, that only a fourth are engaged in agriculture, that nearly a fourth of the wage-earning group were unemployed at the census of 1933, and that nearly 60 per cent of the male breadwinners had to live on an income of less than £2 per week. With such low figures for infant mortality it is interesting to consider how far this rate may eventually fall and whether there is some irreducible minimum below which it is not possible to go. In South Australia the rate has declined from 92 deaths per thousand live births in 1900-1904 to 31 in 1936. In the metropolitan area the latest rate is 35. It is the neonatal rate that is specially recalcitrant, but even at this stage of life improvement is clearly possible and is, in fact, taking place. In the latest years a third of the total mortality under one year of age was attributed to premature birth, 15 per cent to malformations, about 8 or 9 per cent each to congenital debility and injury at birth, 10 per cent to pneumonia, and only 3.5 per cent to diarrhea and enteritis. These figures show the direction that efforts for the saving of infant life must take and suggest that a considerable reduction of the world's record is still possible.

MATERNAL NUTRITION AND NEONATAL DEATHS

Dr. Jefferis Turner, director of infant welfare in Queensland, has drawn attention to the decrease in neonatal mortality following on adequate maternal nutrition. The infant mortality rates in Queensland and South Australia used to be equal. Since 1931, however, the rate in South Australia has been lower and was much lower in 1936, when it reached to within one

decimal point of the New Zealand rate, the lowest in the world. To explain this difference, a comparison was made of the mortality rates for the first month and for the next eleven months of the two states. Of the deaths during the first month, 86 per cent occurred during the first week. All were due to what have been classified as antenatal causes. In the years 1934-1936 the mortality rate in Queensland during the eleven months following the first month has been consistently lower than in South Australia. As infants are rarely brought to child welfare centers during the first week (in which about 86 per cent of this mortality occurs), the lower mortality rates during the first month in South Australia in comparison with Queensland cannot be due to the work of these centers. There is no reason to think that the management at birth is greatly superior in South Australia, so that neonatal or first month mortality can have been reduced only by improved health of the mothers. The facts point to better nutrition as the real cause. The last seven years have been years of economic depression and unemployment and it is the unemployed people who are most exposed to the dangers of malnutrition. In Queensland, the most important cause of malnutrition among women is the deficiency of milk in their diet. Much of this is due to want of knowledge but is aggravated by economic stringency. In South Australia during the "depression," the government adopted the policy of supplying milk rations to the families of the unemployed. Distribution of milk to children and mothers commenced in 1930. In 1935 the South Australian government, on the advice of a committee of the British Medical Association, added to the rations distributed one pint of milk daily to every child up to 6 years of age, half a pint to children between 6 and 13 years, and one and a half pints to expectant and nursing mothers. The milk ration is issued to every mother on production of a medical certificate of pregnancy and evidence that she is in economic need. In Dr. Turner's opinion, the addition of milk to other rations is an adequate explanation of the difference in neonatal mortality rates.

A New Virus Disease

Investigations following the occurrence of a number of cases of fever among workers in a large meatworks in Brisbane have shown that there is in Queensland a fever entity of a type not previously differentiated. It has been provisionally named Q fever. It has certain resemblances to typhus, which in several forms is endemic in Queensland, but is distinguished from it by the absence of a characteristic rash and by the negative response to the Weil-Felix test. Dr. E. H. Derrick of Brisbane has reported these research studies. The onset is acute, the first complaints being malaise, anorexia, headache, pains in the back and limbs, and fever, rising rapidly and remaining usually between 102 and 104 F. Two types may be distinguished. In some cases there is a rapid subsidence after six to nine days; in others the course is protracted to the third or fourth week and the fall of temperature is gradual. The most striking symptom is severe and persistent headache. The pulse rate at the beginning of the illness in comparison with the height of the fever is slow. None of the cases so far have been fatal. Guinea pigs are susceptible to infection from blood or urine from human patients or from blood or organ emulsion from infected laboratory animals. Infected guinea pigs show an incubation period of from two to eighteen days, followed by a fever of from four to six days' duration. Occasionally the infection is inapparent but may be shown to have occurred by the fact that blood or tissues about two weeks after inoculation transmit the infection and that the animal is found afterward to be immune. The infecting agent of Q fever is present in the blood of human patients during the fever period and may be present in the urine in later stages. It is also present in the blood and liver of infected guinea pigs and minute amounts of these will transmit the infection to other guinea pigs. The virus contained in a

liver emulsion may maintain its power to infect for several months if kept in the refrigerator at a temperature of about 5 C., the loss of potency being gradual. Despite considerable work, the epidemiology of Q fever remains obscure. There is no obvious relation to the season. Most of the cases occurred in meat workers or dairy farmers. Attempts to infect in ways other than by subcutaneous or intraperitoneal injection have not been successful, and it has been shown that ingestion of infected tissues could not be the method of natural spread of the fever. The abundance of the virus in the blood, and the ease with which the disease may be transmitted by injection, render it likely that some blood-sucking vector is responsible for the natural transmission and that there is a reservoir of infection in some animal. Attempts to find such a reservoir have so far failed.

EXPERIMENTAL STUDIES

On the hypothesis that a filtrable virus was responsible for the febrile reaction in guinea pigs, studies were made at the Walter and Eliza Hall Institute, Melbourne. No characteristic changes were found in the organs of the infected guinea pigs. Attempts to cultivate bacteria or *Leptospira*, and appropriate microscopic examinations for *Leptospira* were without result. The virus produces characteristic pathogenic effects on monkeys and mice and an inapparent infection in albino rats. The virus survives but does not produce characteristic lesions on the chorio-allantois of the developing egg. It is filtrable with difficulty through relatively permeable (0.7 micron) gradocol membranes. Mice inoculated intraperitoneally show enlargement of the spleen and liver with characteristic microscopic changes. Smears from the cut surface of the spleen, suitably stained, show the presence in variable numbers of intracellularly situated bodies which appear to be typical Rickettsiae. A satisfactory method of staining the organisms has not been obtained, but in smears stained by Castaneda's method the organisms take the form of tiny rods less than 1 micron in length and about 0.3 micron across; the shape varies from well marked rods to coccoid forms indistinguishable from those of psittacosis. Most of them appear blue but paler than psittacosis bodies, and in many clumps a large proportion of the Rickettsiae are pink. A proportion is usually found extracellular but the appearances suggest that all are initially intracellular, where they give rise to cytoplasmic microcolonies, sometimes relatively sharply defined, at other times with a fairly diffuse distribution of Rickettsiae through the cytoplasm. Except that the majority of the bodies are rod shaped, the general appearance of a smear is similar to that obtained from psittacosis-infected spleens. The accumulations range from about 3 to 12 microns in diameter and are usually sharply circumscribed with an oval or circular outline. The Rickettsiae were found in mouse spleen and liver in practically every instance when the tissues were infective and never in control mice treated in various ways. Typical Q fever Rickettsiae have been found in the spleens of mice inoculated with blood taken from a patient in the early stages of the disease, so that there is strong evidence to suggest that Q fever is Rickettsiae. Agglutination of semipurified Rickettsia suspensions from infected mouse tissues by immune human, monkey and guinea pig serums has been observed. Such suspensions are agglutinated to variable titer by serum taken from patients from ten to fifteen days after the onset of symptoms. The test is specific for Q fever infections and is a useful diagnostic method. No further information on the relation of the Q fever Rickettsiae to the classic forms is available. The absence of agglutination by a serum of known high content in X 19 agglutinins is a further indication that the condition bears no relation to typhus. There are some resemblances between the pathology of psittacosis infection in the mouse and that of Q fever, and Lillie in 1930 considered that the virus of psittacosis should be regarded as a Rickettsia. For these reasons limited cross immunity experiments were carried out. Mice immune

to Q fever were inoculated with an active strain of psittacosis and died with typical postmortem signs in the same time as control mice of the same age. It is considered that the Rickettsiae and the disease they cause are distinct from any previously described, but direct immunologic comparison with the various spotted fever (tick-borne) types will be necessary before this can be finally stated.

Possible Influx of European Practitioners into Australia

Toward the end of last year the question arose in Australia of the danger of an invasion on medical practice by foreign graduates. Recent legislation enacted in Tasmania requires any person applying for registration to be in the possession of a qualification obtained in a country which has reciprocity with Tasmania. It is also necessary that the whole of the course of study entitling the holder to his diploma should have been carried out in the country granting the qualification. The passing of legislation similar to this in states other than Tasmania would not remedy the matter, as a person who had, for example, done half his course of study in Melbourne and half in Sidney would not be eligible for registration in Tasmania. At the last meeting of the federal council of the British Medical Association it was resolved that a committee should be appointed to draft a clause which would be suitable for all states.

Trachoma in Western Queensland

Eye diseases have a high incidence among the children of Western Queensland and are a big factor in the conquest and control of the less fertile inland areas. Queensland, with its long western frontier against the inland desert country, where dust, dirt and flies combine to render the eyes susceptible, requires special provisions for the fight against trachoma. The state government, through the officers of the school medical service, seeks out affected children in western schools and homes, and, with the parent's consent, arranges for them to be brought to Brisbane, where they receive treatment for their eyes, together with school work specially suited to the individual capacity of each child, and additional training in domestic science for the girls and manual work for the boys. The results so far obtained have been encouraging. Almost every one of the 200 children who have passed through a special ophthalmic hostel since its foundation nine years ago have been cured of trachoma. After an average stay of eighteen months the children are sent back to their homes able to fulfil their normal life in the community. The expenditure of £30,000 on rebuilding the hostel is considered not large in view of the work it is doing. Provision for sixty-four children is none too great, for the director of school medical services and the ophthalmic surgeon in attendance, both of whom have wide knowledge of the actual conditions in the west, are of the opinion that trachoma is still very prevalent and that, if all the children who require treatment could have such advantages as those which they enjoy in the ophthalmic hostel in Brisbane, trachoma would soon cease to exist in the western districts of Queensland.

Hospital Treatment of Scarlet Fever

Contending that scarlet fever is only one of a number of streptococcal infections, Dr. F. V. Scholes of Melbourne asks why it is deemed necessary to notify, isolate and treat all cases of scarlet fever while the majority of all cases of infection by hemolytic streptococci can be ignored with regard to notification and isolation. Scarlet fever is merely the manifestation of certain symptoms in certain subjects. In others who are equally infectious the syndrome is absent, and they are therefore not suffering from scarlet fever in the strict sense of the term. Epidemics of sickness characterized by follicular tonsillitis, with or without otitis media, by nephritis and by cervical adenitis do not differ essentially from epidemics of scarlet fever. Tonsillitis in one member of a household is often followed by scarlet

fever in another and possibly otitis or nephritis in a third. The same streptococcus has caused all of them and the symptoms of scarlet fever are merely a result in a particular individual. Dr. Scholes suggests that cases of acute tonsillitis and otitis should be investigated bacteriologically just as are cases of scarlet fever and diphtheria and that, if practicable, isolation and treatment should be carried out at home but that, if this cannot be done, the patients should be received in a hospital. All common types of scarlet fever have been found capable of causing scarlet fever, given the proper person. A population of scarlet fever patients, therefore, brought from different localities and aggregated in a fever hospital will be found on admission to be infected with differing strains or types of streptococci. To control direct transmission also Dr. Scholes urges individual isolation of patients until typed, either in cubicles or by barrier nursing in small wards; segregation of patients according to type, in wards of suitable size, according to the number of patients infected by each type (for this purpose subdivisible wards are advocated), and segregation according to type in separate convalescent wards when the walking convalescent stage is reached. By the adoption of these methods it is considered that the majority of young children with uncomplicated scarlet fever will make an uninterrupted recovery and that the state of those in whom infectivity is prolonged, now so often punctuated by a succession of complications and cross infections, will be a rare instead of a common feature.

Hydatid Disease in Australasia

Australia and New Zealand are the only English speaking countries in which hydatid disease is common. The large number of sheep, cattle and dogs give rise to a favorable milieu for the spread of hydatid disease. Two years ago the nucleus of a department for hydatid disease research and prevention was instituted at the New Zealand Medical School under the direction of Dr. C. E. Hercus, professor of public health, Dr. E. F. D'Ath, professor of pathology, and Sir Louis Barnett, emeritus professor of surgery. In New Zealand the human incidence of the disease has increased during the past ten years. At present a reasonable estimate is that from 100 to 150 cases out of a population of 1,500,000 occur every year, and the mortality rate is about 15 per cent. Argentina and Uruguay, important competitors with us in pastoral pursuits, are much more heavily infested. New Zealand has been carrying on a vigorous campaign for the prevention of hydatid disease. Posters and folders have been widely distributed among the farming community, schools, abattoirs and freezing works.

Marriages

LOUIS ZIMMERMAN, Elmsford, N. Y., to Miss Mildred E. Choper of Woodbridge, N. J., in New York, April 11.

HERBERT HAMMOND OGBURN, Greensboro, N. C., to Miss Bobbie Gene Truesdale of Mount Holly, February 12.

JOHN MACMILLAN TOWNSEND, Birmingham, Ala., to Miss Ann Kemper of Owenton, Ky., February 5.

KENNETH L. SHAFFER, Corydon, Ind., to Miss Annabelle Nafe of Kewanna, in Lafayette, February 20.

CHARLES W. NEUHARDT, Yonkers, N. Y., to Miss Ruth T. Vogel of New Hartford, Conn., in January.

LEONARD JAY TRILLING, Paterson, N. J., to Miss Beatrice Sulzberger of New York, April 14.

ROBERT NOVAK, Brookville, Ohio, to Miss Wilda Corts of Coffeyville, Kan., in February.

CLETUS T. KEARNEY, Gridley, Ill., to Miss Helen Garm of Beardstown, February 26.

G. ROBERT MATTHEWS JR. to Miss Virginia R. Elliott, both of York, Pa., April 26.

GEORGE A. ZINDLER to Miss Florence Mary Rudell, both of Detroit, April 23.

Deaths

Paul J. Pontius * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1891; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; ophthalmologist to St. Joseph's Hospital, Philadelphia, Masonic Home, Elizabethtown; consulting surgeon to the Wills Hospital; consulting ophthalmologist to the Philadelphia General and Frankford hospitals, Shriners' Hospital for Crippled Children, Philadelphia, and Grand View Hospital, Sellersville; in 1932 received the honorary degree of doctor of science from Bucknell College, Lewisburg, Pa.; aged 70; died, February 16, of carcinoma of the bladder.

Wade Hampton Frost * Baltimore; University of Virginia Department of Medicine, Charlottesville, 1903; dean of Johns Hopkins School of Hygiene and Public Health, 1931-1934, resident lecturer in epidemiology, 1919-1921, and since 1921 professor; associated with the U. S. Public Health Service from 1905 to 1929; director of the bureau of sanitary service of the American Red Cross during the World War; author of monographs in the field of sanitary science and epidemiology; aged 58; died, May 1, in the Johns Hopkins Hospital, of carcinoma of the esophagus.

Thomas William Harvey * Orange, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878; past president of the Medical Society of New Jersey and the Essex County Medical Society; fellow of the American College of Surgeons; formerly member of the board of education; city physician, and secretary of the board of health, 1880-1884; consulting surgeon to the Orange Memorial Hospital and the New Jersey Orthopedic Hospital; aged 84; died, April 8, of arteriosclerosis.

Mildred Clark Clough * Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1914; instructor in clinical medicine at her alma mater, 1916-1921; teacher of physiology, Maryland State Teachers College, 1919-1922; physician in charge, venereal disease clinic (for women), city health department, 1926-1932; co-author of the ninth edition of "Practical Bacteriology, Hematology and Animal Parasitology"; aged 49; died, March 11, of bronchopneumonia following osteomyelitis and pyelitis.

William F. Elgin * Glen Olden, Pa.; University of Maryland School of Medicine, Baltimore, 1887; director of the H. K. Mulford Vaccine Laboratory of Philadelphia from 1898 to 1929, when the company was acquired by Sharp & Dohme and he became director of the vaccine division; retired March 15, 1938; member of the Medical and Chirurgical Faculty of Maryland; author of numerous articles on the production of vaccines; aged 76; died, April 18, of bronchopneumonia and cerebral hemorrhage.

Stephen Webb Davis * Charlotte, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1927; formerly secretary of the Mecklenburg County Medical Society; served during the World War; fellow of the American College of Physicians; secretary and member of the staff of the Presbyterian Hospital; on the staffs of the Mercy Hospital and the New Charlotte Sanatorium; aged 43; died, March 16, of a self-inflicted bullet wound.

Sanford Withers * Denver; Washington University School of Medicine, St. Louis, 1919; member of the Radiological Society of North America, American College of Radiology and the American Radium Society; fellow of the American College of Physicians; served during the World War; on the staff of the Denver General Hospital; aged 46; died, March 8, in New York, of aplastic anemia and bronchopneumonia.

Ross Vernet Patterson * Philadelphia; Jefferson Medical College of Philadelphia, 1904; dean and Sutherland M. Prevost professor of therapeutics at his alma mater; past president of the Medical Society of the State of Pennsylvania and the Association of American Medical Colleges; served during the World War; received honorary degrees from several colleges; aged 60; died, May 2, in the Jefferson Hospital.

Eugene E. Tupper, Eau Claire, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the State Medical Society of Wisconsin; past president and secretary of the Eau Claire Dunn-Pepin Counties Medical Society; on the staff of the Luther Hospital; aged 67; died, February 24, of pulmonary tuberculosis and lobar pneumonia.

Paul Eaton * Jacksonville, Fla.; Western Pennsylvania Medical College, Pittsburgh, 1903; formerly associate professor of preventive medicine at the University of Georgia School of Medicine, Augusta; director of the diagnostic laboratories, state board of health; aged 62; died, February 25, in the Riverside Hospital, of heart disease, paralysis agitans and bronchopneumonia.

Elmer Ellsworth Brinckerhoff * Oakland, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; member of the Pacific Coast Oto-Ophthalmological Society; at various times on the staffs of the Alameda County, Providence and Peralta hospitals; aged 55; died, March 12, of chronic nephritis and pulmonary tuberculosis.

Guy Stark Saffold, Washington, D. C.; George Washington University School of Medicine, Washington, 1905; member of the Medical Society of the District of Columbia; served during the World War; formerly on the staff of the Episcopal Eye, Ear and Throat Hospital; aged 57; died, February 27, of carcinoma of the larynx.

Thomas Smith O'Connell * East Hartford, Conn.; College of Physicians and Surgeons, Baltimore, 1892; for many years member of the board of education and formerly member of the state legislature; aged 71; died, February 25, in St. Francis Hospital, Hartford, of chronic osteomyelitis of the vertebrae with abscess formation.

Charles Dalton Cleghorn, Miami, Fla.; Columbia University College of Physicians and Surgeons, New York, 1904; member of the Florida Medical Association and the Radiological Society of North America; superintendent of the Macon (Ga.) Hospital, 1916-1918; aged 59; died, March 25, of pulmonary tuberculosis.

Leslie Boyd Seaport, Cohoes, N. Y.; Albany Medical College, 1916; member of the Medical Society of the State of New York; served during the World War; aged 47; on the staff of the Cohoes Hospital, where he died, February 20, of acute perforated gangrenous appendicitis and peritonitis.

Loren Ray Weir, New Britain, Conn.; Kansas City (Mo.) Hahnemann Medical College, 1915; member of the Connecticut State Medical Society; served during the World War; on the staff of the New Britain General Hospital; aged 53; died suddenly, February 10, of acute coronary occlusion.

Frank Holmes Smith * San Bruno, Calif.; Cooper Medical College, San Francisco, 1905; past president of the San Mateo County Medical Society; aged 58; on the staff of the Mills Memorial Hospital, San Mateo, where he died in February of gunshot wounds inflicted by a patient.

Joseph H. Cooper, Tuscaloosa, Ala.; Chattanooga (Tenn.) Medical College, 1904; veteran of the Spanish-American War; aged 64; died, March 16, in the Veterans Administration Facility, Atlanta, of surgical shock following the second stage operation for suprapubic prostatectomy.

Daniel Joseph Devlin Jr., * Assistant Surgeon, U. S. Public Health Service, Reserve, New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1933; on the staff of the U. S. Marine Hospital; aged 28; died suddenly, March 14, of heart disease.

John William McLean, Godwin, N. C.; Davidson (N. C.) School of Medicine, 1902; member of the Medical Society of the State of North Carolina; member of the county board of health; aged 63; died suddenly, February 28, in Ventnor, N. J., of arteriosclerotic myocarditis.

Frank Montague Shipman, Denver; St. Louis College of Physicians and Surgeons, 1908; health officer of Aurora and member of the school board; on the staffs of the Porter Sanitarium and Hospital and Mercy Hospital; aged 55; died, February 21, of lobar pneumonia.

Lot E. Alexander, Pendleton, Ind.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; member of the Indiana State Medical Association; formerly member and secretary of the board of education; aged 84; died, February 8, at Milroy, Pa., of senility.

Lilian Welsh, Columbia, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1889; professor emeritus of physiology and hygiene at Goucher College, Baltimore; in 1924 received the honorary degree of LL.D. from Goucher College; aged 79; died February 23.

George S. Ray, Erie, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; on the staff of St. Vincent's Hospital; aged 67; died, February 20, of heart disease and hypertension.

George Patrick Quinn, Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1928; member of the Louisiana State Medical Society; formerly director of health in the public schools; aged 35; was drowned, February 1, in the Mississippi River.

James H. Bennett, Youngstown, Ohio; Western Reserve University Medical Department, Cleveland, 1887; for many years member and president of the board of education; aged 78; died, March 2, of arteriosclerosis, cerebral hemorrhage and hypertrophy of the prostate.

Vera Heinly Jones ☉ Denver; University of Colorado School of Medicine, Denver, 1925; director of maternal and child health and care of crippled children under the state board of health and the social security administration; aged 40; was drowned, February 16.

John Franklin Williams, Monticello, Fla.; Atlanta Medical College, 1897; member of the Florida Medical Association; on the associate staff of the John D. Archbold Memorial Hospital, Thomasville, Ga.; aged 71; died, February 6, in St. Vincent's Hospital, Jacksonville.

George Edward Leete, Concord, N. H.; Dartmouth Medical School, Hanover, 1877; member of the New Hampshire Medical Society; at one time member of the school board and board of health of Canaan; aged 86; died, February 22, of cerebral hemorrhage.

Ernest Don Smith, Fort Wayne, Ind.; Fort Wayne College of Medicine, 1896; member of the Indiana State Medical Association; on the staffs of the Methodist and Lutheran hospitals; aged 63; died, February 26, in St. John's Hospital, Springfield, Ill., of hypertension.

Jasper William Jolley, Marion, Ohio; Starling Medical College, Columbus, 1905; member of the Ohio State Medical Association; served during the World War; aged 57; died, February 13, at Rochester, Minn., of hemorrhage following an intestinal operation.

Charles Neumann Gelber ☉ New York; Long Island College Hospital, Brooklyn, 1913; member of the American Academy of Ophthalmology and Oto-Laryngology; formerly medical director of the Gelber Hospital; aged 46; died, March 3, of coronary sclerosis.

William H. Cox, Brooksville, Fla.; Chattanooga (Tenn.) Medical College, 1893; formerly state health officer and secretary of the state board of health; state prison physician from June 1928 to June 1932; aged 75; died, March 4, of nephritis and uremia.

Robert E. Crabtree, Amsterdam, Mo.; University Medical College of Kansas City, 1900; member of the Missouri State Medical Association; served during the World War; aged 67; died, March 14, in the Research Hospital, Kansas City, of encephalitis.

Leon Oscar Davis ☉ Philadelphia; Medico-Chirurgical College of Philadelphia, 1914; instructor in surgery, Temple University School of Medicine; on the staff of the Temple University Hospital; aged 48; died, February 27, of coronary thrombosis.

William Woodward Easterling, Lake Village, Ark.; University of the City of New York Medical Department, 1889; member of the Arkansas Medical Society; county health officer; aged 68; died, February 21, of heart disease and hypostatic pneumonia.

John P. Sudderth, Nowata, Okla.; Southern Medical College, Atlanta, 1891; member of the Oklahoma State Medical Association; formerly county health officer; on the staff of the Nowata Hospital; aged 69; died, February 15, of cirrhosis of the liver.

Robert Staunton Adams ☉ Wexford, Pa.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; member of the Medical Society of the State of New York; aged 71; died, February 28, of a cerebral hemorrhage.

Ernest G. Dittmer, Manchester, Iowa; Chicago Homeopathic Medical College, 1895; member of the Iowa State Medical Society; mayor; past president of the Delaware County Medical Society; aged 68; died, March 14, of cerebral hemorrhage.

Perry Franklin Bullington, Chico, Calif.; Eclectic Medical Institute, Cincinnati, 1892; Cooper Medical College, San Francisco, 1908; formerly health officer and president of the board of education; aged 71; died, March 5, in San Francisco, of uremia.

Grover Barney Woodard ☉ Wilson, N. C.; Medical College of Virginia, Richmond, 1915; past president of the Wilson County Medical Society; on the staff of the Mercy Hospital; aged 47; died, February 26, in the Memorial Hospital, Richmond, Va.

Harry Hyman Blond, Los Angeles; McGill University Faculty of Medicine, Montreal, Que., Canada, 1931; member of the California Medical Association; on the staff of Cedars of Lebanon Hospital; aged 31; died, March 12, of heart disease.

Thomas G. Parker, Racine, Wis.; Illinois Medical College, Chicago, 1907; served during the World War; on the staff of St. Luke's Hospital; aged 65; died, February 22, of cerebral hemorrhage with bulbar paralysis and fracture of the left femur.

Charles L. Maine, Du Bois, Pa.; College of Physicians and Surgeons, Baltimore, 1892; member of the Medical Society of the State of Pennsylvania; on the staff of the Maple Avenue Hospital; aged 72; died, February 11, of coronary sclerosis.

William Alex Quinn, Lakeland, Ky.; Louisville (Ky.) Medical College, 1883; at one time member of the state and county boards of health; formerly superintendent of the Central State Hospital; aged 77; died, February 27, of pneumonia.

Ira McConaughy Roadman, Minneapolis; University of Minnesota Medical School, Minneapolis, 1898; served during the World War; aged 72; died, February 14, at Mexico City, of peritonitis following an operation for acute appendicitis.

David B. Beggs, Wilkinsburg, Pa.; Jefferson Medical College of Philadelphia, 1899; member of the Medical Society of the State of Pennsylvania; formerly public school physician; aged 70; died, February 25, of cerebral hemorrhage.

Wunibald John Probst, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1908; served during the World War; aged 52; on the staff of the Mercy Hospital, where he died, February 8, of arteriosclerotic heart disease.

George Marion Bumgarner, Richmond, Calif.; Beaumont Hospital Medical College, St. Louis, 1892; served during the World War; aged 66; died, March 15, in a hospital at Palo Alto, of arteriosclerosis and cerebral hemorrhage.

Ernest Antonio Lopez, San Leandro, Calif.; Indiana University School of Medicine, Indianapolis, 1924; member of the California Medical Association; aged 40; died, February 1, in the Peralta Hospital, Oakland, of brain tumor.

Francis Errett Roberts, Moundsville, W. Va.; Johns Hopkins University School of Medicine, Baltimore, 1916; member of the American Urological Association; aged 47; died, February 6, of pulmonary and intestinal tuberculosis.

Leslie Brand, Maysville, Ky.; Baltimore Medical College, 1901; formerly member of the board of education; aged 65; died, March 22, in the Harrison Memorial Hospital, Cynthia, of injuries received in an automobile accident.

Thomas Benton Crisp ☉ Washington, D. C.; George Washington University School of Medicine, Washington, 1919; aged 45; died, March 20, in the Walter Reed General Hospital, of cerebral hemorrhage and arterial hypertension.

Joseph David Hall, Readyville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1883; member of the Tennessee State Medical Association; aged 83; died, February 27, of carcinomatosis and intestinal obstruction.

Benaiah R. Job, Cottage Grove, Ore.; University of Oregon Medical School, Portland, 1897; member of the Oregon State Medical Society; formerly mayor, and city health officer; aged 78; died, February 16, of chronic nephritis.

Francis Anthony Auleta, New York; University and Bellevue Hospital Medical College, New York, 1901; served during the World War; aged 58; died, March 10, in the Roosevelt Hospital, of subacute bacterial endocarditis.

Robert Cade Parrish ☉ Philadelphia; Medico-Chirurgical College of Philadelphia, 1898; district medical supervisor of the city public schools; served during the World War; aged 61; died, February 1, of cardiovascular disease.

William K. Dolan, Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1880; member of the Medical Society of the State of Pennsylvania; aged 83; died, February 28, of carcinoma of the prostate.

Robert Lee Seward, Isle of Wight, Va.; University of Maryland School of Medicine, Baltimore, 1891; member of the Medical Society of Virginia; for many years member of the school board; aged 75; died, January 31.

Emanuel Goodman, San Francisco; Medical College of Ohio, Cincinnati, 1892; member of the California Medical Association; aged 82; died, February 22, in the Mount Zion Hospital of arteriosclerosis and bronchopneumonia.

Gaetano Gerardo Petrocelli, Waterbury, Conn.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1905; aged 60; died, March 23, of cerebral hemorrhage, coronary disease and arterial hypertension.

Benjamin Leslie Harrison, Trumann, Ark.; Barnes Medical College, St. Louis, 1899; member of the Arkansas Medical Society; aged 70; died, February 19, in St. Bernard's Hospital, Jonesboro, of bronchopneumonia.

Louis Altman * New York; St. Louis University School of Medicine, 1927; aged 36; on the staffs of the Jewish Maternity Hospital and Beth Israel Hospital, where he died, March 22, of a staphylococcal infection.

William Alonzo Ostrander, Smethport, Pa.; Jefferson Medical College of Philadelphia, 1899; served during the World War; aged 65; died, February 12, in the Community Hospital, Kane, of cerebral hemorrhage.

Henry Augustus Elliot, Barnet, Vt.; University of Vermont College of Medicine, Burlington, 1893; formerly member of the state legislature; aged 70; died, March 31, in the Brightlook Hospital, St. Johnsbury.

Semmie Moberly, Little Rock, Ark.; Eclectic Medical University, Kansas City, Mo., 1918; served during the World War; aged 42; died, February 25, in the Veterans Administration Facility of lobar pneumonia.

Alfred Edwin McRitchie, Qu'Appelle, Sask., Canada; Western University Faculty of Medicine, London, Ont., 1911; aged 48; died, January 6, in the Union Hospital, Indian Head, of staphylococcal septicemia.

Gipson Benjamin Mack * Auburn, N. Y.; New York Homeopathic Medical College and Hospital, 1904; on the staffs of the City Hospital and the Mercy Hospital; aged 72; died, February 27, of encephalitis.

Jeffery Charles Douville * North East, Pa.; University of Maryland School of Medicine, Baltimore, 1893; aged 72; died, February 2, in St. Vincent's Hospital, Erie, of bronchopneumonia and arteriosclerosis.

Charles Perry Horner, Enid, Okla.; Northwestern University Medical School, Chicago, 1899; member of the Illinois State Medical Society; aged 64; died, February 6, in a local hospital of cerebral hemorrhage.

Charles H. Barnstein, Newton, Wis.; Milwaukee Medical College, 1906; member of the State Medical Society of Wisconsin; aged 57; died, March 4, of hypostatic pneumonia and coronary thrombosis.

Adin Henry Foster, Erie, Ill.; Keokuk (Iowa) Medical College, 1905; member of the Illinois State Medical Society; aged 72; died, March 3, in the Mercy Hospital, Davenport, Iowa, of myocarditis.

John James Gill, Chatham, La.; Memphis (Tenn.) Hospital Medical College, 1891; member of the Louisiana State Medical Society; aged 71; died, February 23, in the Ruston-Lincoln Sanitarium, Ruston.

Louis D. Barbot, Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1892; aged 70; died, March 24, in St. Francis Xavier Infirmary of paralytic ileus and coronary sclerosis.

Nathaniel Selleck * Danbury, Conn.; University of the City of New York Medical Department, 1891; on the staff of the Danbury Hospital; aged 69; died, March 13, of carcinoma of the stomach.

William Marvin O'Cain, Jasper, Fla.; Atlanta College of Physicians and Surgeons, 1900; aged 65; died, February 5, in River Junction of hypostatic pneumonia, furunculosis and an infected arm.

George Franklin Roberts, Lexington, S. C.; University of Tennessee Medical Department, Nashville, 1908; member of the South Carolina Medical Association; aged 55; died, January 22, in Columbia.

Charles Morris Quimby * Gloucester, Mass.; Maryland Medical College, Baltimore, 1904; on the staff of the Addison Gilbert Hospital; aged 68; died, February 25, of coronary occlusion.

Millard Henry Crawford, Charlottesville, Va.; University of the City of New York Medical Department, 1874; at one time served in the navy; aged 85; died March 20, of cardiac embolus.

Julian E. Tilman, Powhatan, Va.; Medical College of Virginia, Richmond, 1900; formerly county coroner and chairman of the board of health; aged 61; died, February 25, of heart disease.

G. W. Sherrer, Rayle, Ga.; University of Georgia Medical Department, Augusta, 1876; member of the Medical Association of Georgia; Confederate veteran; aged 90; died, February 26.

Earle C. Glenn, Sandy Lake, Pa.; Baltimore Medical College, 1903; aged 62; died, February 24, in the Mercer County Home and Hospital, Mercer, of heart disease and tuberculosis.

John McElhenny Grubbs, Seward, Pa.; Miami Medical University, Columbus, 1886; aged 80; died, February 10, in the Lee Homeopathic Hospital, Johnstown, of cerebral hemorrhage.

Frederic Thomas Masengill, Jonesboro, Tenn.; Hospital College of Medicine, Louisville, Ky., 1898; served during the World War; aged 63; died, February 28, of myocarditis.

Otto Fred Heidrich, Pasadena, Calif.; University of Minnesota Medical School, Minneapolis, 1936; aged 28; died, February 16, of carcinomatosis and teratoma of the testicle.

Richard F. Duncan, Tompkinsville, Ky.; University of Louisville (Ky.) Medical Department, 1886; served during the World War; aged 74; died, March 25, of spinal sclerosis.

Joseph Harry Honnet, Wilmington, N. C.; Columbia University College of Physicians and Surgeons, New York, 1900; aged 63; died, February 28, of coronary thrombosis.

Every Paul Lunderville * Berlin, N. H.; University of Vermont College of Medicine, Burlington, 1896; also a pharmacist; aged 63; died, February 4, of acute nephritis.

Frederick Lewis Baker, Philadelphia; Medico-Chirurgical College of Philadelphia, 1895; served during the World War; aged 72; died, February 27, of arteriosclerosis.

John W. Greenman, Galesburg, Ill.; Keokuk (Iowa) Medical College, 1898; aged 63; died, February 22, in Clermont, Fla., of uremia, nephritis and cerebral hemorrhage.

Harry de Nell Williams, San Francisco; College of Physicians and Surgeons of San Francisco, 1906; aged 58; died, February 18, of a self-inflicted bullet wound.

Homer S. Bruce * Opelika, Ala.; Atlanta Medical College, 1891; formerly on the staff of the East Alabama Hospital; aged 64; died, March 12, of coronary thrombosis.

James Max Keaton, Asheville, N. C.; Howard University College of Medicine, Washington, D. C., 1917; aged 59; died, February 22, of acute dilatation of the heart.

William Lowry Arnold, Church Hill, Tenn.; University of Tennessee Medical Department, Nashville, 1901; aged 63; died, March 11, of cerebral hemorrhage.

Donald Eugene Harris, Los Angeles; Medical College of Ohio, Cincinnati, 1902; aged 60; died, February 18, of traumatic fracture of the sixth cervical vertebra.

Clarence Frederick Bass, Chattanooga, Tenn.; Meharry Medical College, Nashville, 1916; aged 52; died, March 3, of cardiac insufficiency and thrombosis.

John A. Ferguson, Memphis, Tenn.; University of Louisville (Ky.) Medical Department, 1895; aged 75; died, March 14, in the Western State Hospital.

Frank Benjamin Cogswell * Washington, D. C.; Hering Medical College, Chicago, 1908; aged 53; died, March 28, of cerebral hemorrhage and uremia.

Frank Taylor, Hazleton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; aged 65; died, February 21, of chronic myocarditis.

Walter P. Deakins, Wildwood, Ga.; University of Tennessee Medical Department, Nashville, Tenn., 1892; aged 71; died, February 28, of influenza.

Alva Burton Burris, Salisbury, Md.; Hahnemann Medical College and Hospital of Philadelphia, 1909; aged 65; died, March 25, in a local hospital.

Robert E. Darby, Springfield, Mo.; University Medical College of Kansas City, Mo., 1893; also a dentist; aged 73; died, March 9, of lobar pneumonia.

Jephtha Dickey Davis, Fort Thomas, Ky.; Medical College of Ohio, Cincinnati, 1890; aged 72; died, March 25, in Coral Gables, Fla., of heart disease.

Edward Wray Crockett, Macclenny, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916; aged 47; was shot and killed, February 24.

Platt Welch Upshaw, Galena, Kan.; American Medical College, St. Louis, 1892; aged 66; died, February 24, in St. John's Hospital, Joplin, Mo.

William Henry Gunther, Sheboygan, Wis.; Rush Medical College, Chicago, 1883; aged 78; died, March 27, of arteriosclerosis.

Correspondence

THE MODE OF ACTION OF SULFANILAMIDE

To the Editor:—In a communication in THE JOURNAL, April 9, Elizabeth S. Hemmens and G. M. Dack called attention to an ambiguity in our article on the mode of action of sulfanilamide in THE JOURNAL, January 29, page 349.

We state in the summary: "The major action of sulfanilamide on the beta hemolytic streptococcus seems to be neutralization of the toxins." We used the word "neutralization" in its general sense of "to render inert the peculiar properties of" rather than in the chemical sense of "chemically combine with and destroy." We used the plural "toxins" to indicate that we were not referring solely to hemotoxin. It is evident from this communication and from letters which we have received that the word "neutralization" was poorly chosen and that we should have said: "The major action of sulfanilamide appears to be on the production of toxins or aggressins. We do not yet know to what this is due." We did consider in November 1932, when the article was submitted for publication, that a loose chemical combination with preformed toxin was most probable. We have since been unable to demonstrate by the usual methods any inactivation of preformed hemotoxin. However, it must be remembered that the usual test is based on visible hemolysis produced within one hour and that such concentrations of hemotoxin do not ordinarily accumulate in the body in beta hemolytic streptococcus infections before death. The marrow culture should therefore be more suitable than the ordinary toxin titration for detecting quantities of toxin comparable to what might be produced in human infections.

The degree of bacteriostasis produced by sulfanilamide in broth cultures could hardly produce more than delayed death if it were the only factor operative in therapy with the drug. We are still of the opinion that the major action of sulfanilamide is on the toxins or aggressins which are responsible for the virulence of the organism and which render it relatively immune to bactericidal substances against the beta hemolytic streptococcus present in normal human serum and in monkey serum but not present in the serum of the mouse. We have now more evidence to support the view that bactericidal substances must be present in the serum of the animal, be developed or be introduced from another source if sulfanilamide is to save lives. For example, sulfanilamide alone has only a slight bacteriostatic effect on pneumococcal infections in marrow cultures or broth cultures but sulfanilamide plus type specific antipneumococcus serum is far more effective than either alone. We also have data on a sufficient number of clinical beta hemolytic streptococcus infections treated with only 0.3 to 0.6 Gm. of sulfanilamide every four hours night and day to support our evidence from marrow culture that the previously used large doses are not necessary in beta hemolytic streptococcus infections.

Our observations that the presence of bactericidins in the serum is more necessary than phagocytosis by the cells and that the previously used doses of sulfanilamide are higher than necessary with small inoculations of organisms, such as are found in human infection, have already been confirmed by Hoare (*Lancet* 1:655 [March 19] 1938).

Experiments are cited by Hemmens and Dack with *Bacterium necrophorum* as evidence that the action of sulfanilamide is not on the toxins or aggressins. It is difficult to see why the fact that toxin production by *Bacterium necrophorum* has not yet been demonstrated proves that toxin production by this organism does not occur when it is recalled how many of the gonococcus and meningococcus were studied before

toxin production by these organisms was demonstrated and effective antitoxins were prepared. It is difficult to see how "inhibitory action of the drug on the reproductive rate of the organism" of the degree demonstrated by Long and Bliss and others in ordinary culture mediums could explain the enormous differences in bactericidal power observed by Colebrook, Buttle and O'Meara between sulfanilamide in monkey or human blood and equal concentrations of sulfanilamide in mouse blood, or could explain the differences between our observations in marrow culture or mediums containing human serum and in Hartley broth.

We regret that a poor choice of terms failed to make our meaning clear and appreciate having had this ambiguity called to our attention.

EDWIN E. OSGOOD, M.D.

INEZ E. BROWNLEE, B.A., Portland, Ore.

CYCLOPROPANE AND POSTOPERATIVE ATELECTASIS

To the Editor:—It has come to be accepted in recent years that bronchial obstruction is necessary in the causation of postoperative atelectasis. Jones and Burford (*THE JOURNAL*, April 2, p. 1092) postulate that massive atelectasis can occur in the absence of bronchial obstruction. This view is based on their observations on cyclopropane anesthesia. They maintain that, because the cyclopropane and oxygen are readily absorbed and slowly absorbable nitrogen is in time dissipated, there is a gradual disappearance of gases from the alveoli which could keep them distended. Contributing factors are mentioned, such as quiet, shallow respirations, opiates, the pharmacologic effect of cyclopropane itself and also the high oxygen content in the lungs.

The view which the authors have taken would seem to be at odds with our concepts of the physiology of respiration. One of the fundamental principles involved in this problem is the difference between the intrapleural and the atmospheric pressures. The latter is known to be 6 mm. of mercury higher than the former (for adults). The atmosphere is directly continuous with the bronchi and alveoli, provided the air passages are patent. On inspiration the intrapulmonary pressure is approximately 9 mm. greater than the intrapleural pressure. It is obvious from these facts that atelectasis should not occur no matter how absorbable the gases may be, provided the normal gradient between intrapleural and intrapulmonary pressures is maintained.

That this differential pressure may be maintained during anesthesia is not to be doubted, for atmospheric pressure is exerted on the exterior of the anesthesia bag and, in addition, since the mask is not sealed to the face some air must from time to time be sucked into the air passages. Any quiet shallow breathing that occurs during anesthesia will have little influence in collapsing the lungs, so long as the differential pressure is maintained. The lungs are known to remain distended even after breathing has ceased.

The authors describe a case of their own and three others which came to autopsy. Of one of the latter it is definitely stated that no bronchial obstruction was observed, although this is assumed to have occurred in the others. It is difficult to reconcile the presence of atelectasis in these cases with the absence of bronchial obstruction. It may be suggested that some functional condition such as bronchial spasm or a falling back of the tongue is responsible for the closure of the air passages. Another possibility is the inhalation from an empty bag; I have frequently seen anesthetists practice this procedure toward the end of anesthesia.

There have been no experiments to prove that quickly absorbable gases per se lead to atelectasis; there is on the contrary evidence that this does not occur. Numerous experiments have

been performed in which animals have survived atmospheres of pure oxygen for days (Smith, S.: *J. Physiol.* 24:19, 1899).

The recommendation of the authors that an inert gas such as helium be added to cyclopropane is excellent because it will at least delay atelectasis when bronchial obstruction is present.

JULIUS KAUNITZ, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACTION OF DRUGS ON SYMPATHETIC NERVOUS SYSTEM

To the Editor:—An article by Boyd and Connell (*Am. J. M. Sc.* 194: 768 [Dec.] 1937) describing the action of benzedrine and related substances prompts me to ask a number of questions, some clinical, some pharmacologic. In spinal anesthesia, ephedrine salts are used to combat the falling blood pressure, but it is said that too large a dose of ephedrine may be harmful. This seems to be borne out by the experiments mentioned by Boyd and Connell. They state that previous cocainization enhanced the effect of epinephrine on the blood pressure of rabbits but actually decreased the response to ephedrine and benzedrine compounds. In a number of instances a fall in blood pressure occurred when ephedrine or benzedrine compounds were injected after cocaine. Since I am interested in the treatment of cocaine poisoning, I raise the following questions: In shock even the injection of epinephrine is deprecated, since it tends to trap blood on the arterial side of the circulation and prevent an adequate return to the heart. In cocaine poisoning would epinephrine be indicated and benzedrine and ephedrine possibly contraindicated? Is sodium phenobarbital used in cocaine poisoning only if the patient is in convulsions, or would it be used also on an unconscious patient? What is the proper treatment of cocaine poisoning? Boyd and Connell state that ergotamine diminished but did not reverse the effect of benzedrine and ephedrine in raising blood pressure and concluded that to a certain extent these drugs acted directly on the muscle of the blood vessel, to cause, presumably, vasoconstriction. What is the explanation then of the increase of blood flow, presumably vasodilatation, in the perfusate of ergotamized frogs after ephedrine? The results seem contradictory unless some other factors enter. Will you please state the point of action (muscle, nerve cell or neurocellular junction) of ephedrine, benzedrine and epinephrine, and the reason for the effects of cocaine and ergotamine when used with these drugs.

M.D., Pennsylvania.

ANSWER.—The most generally acceptable explanation of the mechanism of sympathetic responses is that the impulse comes down the sympathetic nerve fiber and liberates epinephrine or some substance closely related to it within the smooth muscle cell. This epinephrine then diffuses from the nerve ending into the contiguous muscle protoplasm at the myoneural junction, where it unites with either sympathin E or sympathin I. This new complex then causes physical or chemical changes in the muscle protoplasm which result in contraction or relaxation.

Cocaine increases the responses to sympathetic nerve stimulation and also to the injection of epinephrine, as was shown by Fröhlich and Loewi in 1910. The best available explanation for the latter effect would seem to be that cocaine makes the smooth muscle cell membrane more permeable, so that injected epinephrine can more readily get through it and thereby produce a sensitized or increased effect. Only a small proportion of smooth muscle cells, however, can be demonstrated to have nerve endings within them. The remainder of the cells are supposedly brought into action by diffusion of epinephrine or epinephrine-sympathin complex into them from muscle cells which do contain sympathetic nerve endings. Cocaine, by making these cell membranes more permeable, would increase the ease of diffusion of the stimulant and thus produce a heightened response. Ergotoxin or other ergot alkaloids block the responses to the augmentor sympathetic impulses not by paralyzing the nerve endings or production of sympathin but apparently by preventing epinephrine-sympathin E complex from reacting with the muscle protoplasm. These concepts cannot be taken as being entirely proved, but they afford the most rational explanation of the facts now available.

It was discovered by Tainter in 1925 that responses to the other amines, such as ephedrine and tyramine, did not follow the pattern of epinephrine reactions, particularly with regard to the cocaine phenomena. He showed that at the time when cocaine sensitized the response to epinephrine it desensitized or abolished the responses to ephedrine, tyramine, benzedrine and propadrine as well as to other less widely known compounds of this sympathomimetic group. The easiest explana-

tion of how these compounds produce sympathetic effects in the uncocainized preparations would be that they stimulated the nerve endings and caused the liberation of epinephrine, thus starting the typical chain of sympathetic activation. However, the cocaine results make this a difficult hypothesis to sustain. More likely possibilities would be that these compounds produce their stimulation beyond the nerve endings either by reacting with the muscle protoplasm directly or by chemically uniting with the sympathins and thereby producing a stimulating material similar to the epinephrine-sympathin complex but not identical with it.

Ergotoxin produces a reversal of sympathetic responses to epinephrine by preventing the responses to the epinephrine-sympathin E augmentor complex. In the blood vessels, this allows the vasodilator action of the epinephrine-sympathin I complex which is liberated simultaneously to be observed in the fall of blood pressure. There is also the possibility of acetylcholine being liberated by these vasodilator fibers and contributing to the sympathetic inhibitor responses.

The sympathetic nervous system of the frog is poorly differentiated in comparison to that of mammals, and particularly man, and the pattern of responses to many sympathetic drugs shows much variation in this species from that of the higher animals. In addition, these reactions are so complex and are so incompletely understood, and the data in many cases contain so many conflicting elements, that no theory can be expected to reconcile completely all the reported observations.

Some of the better established facts have immediate clinical importance. Thus, cocaine abolishes or greatly diminishes the responses to many of these compounds. This has been shown experimentally under a wide variety of conditions, and it has also been demonstrated clinically. Therefore, these epinephrine substitutes cannot be used indiscriminantly for their usual effects on the circulation when cocaine and possibly other local anesthetics are in the body. About the best of the epinephrine substitutes under these conditions is neosynephrine, which chemically is close enough to epinephrine so that its effects are not abolished by the local anesthetic, and yet is sufficiently dissimilar so that its actions are not potentiated. Therefore, in cocaine poisoning neosynephrine would seem to be the drug of choice for stimulating the circulation, rather than epinephrine, the effects of which might be unpredictably potentiated, or the other amines, the effects of which might be greatly diminished or completely abolished.

In poisoning from local anesthetics, phenobarbital is used to depress the central nervous system sufficiently to prevent convulsive seizures. If the patient is not having convulsions but is in a depressed state, administration of a further depressant would seem to be unwise. Probably the most important single measure in preventing catastrophes from local anesthetics is to maintain adequate artificial respiration. If there is a lowered level of blood pressure, this can be combated by cautious doses of epinephrine or, better still, by full doses of neosynephrine. While it is true that in shock or collapse strong vasoconstrictors, such as epinephrine, may tend to pool the blood in the arterial side of the circulation, the more important requirement is to maintain effective levels of pressure and blood flow through the cerebral circulation.

SAFECOTE INSULATING MATERIAL

To the Editor:—An electrician gets a skin eruption on his hands and arms when working with electric wire made by the Parante Cable and Wire Company, the insulating of which is impregnated with "Safecote," which makes it fireproof. Could you tell me what the substance is which might irritate the skin? Other kinds of insulation which are not fireproof do not irritate this man.

W. E. WILSON, M.D., Northfield, Minn.

ANSWER.—The Parante Cable and Wire Company was given an opportunity to furnish precise information as to the nature of "Safecote." Safecote is a copyrighted name applied to a rubber covered cotton-braided building wire, which is treated with compounds to make it moisture and flame resisting. The cotton braid on Safecote wire is first impregnated with a compound known as a saturator consisting of asphalt and stearin pitch. The wire is then given an intermediate coat of a compound consisting of stearin pitch and montan wax. Wire that is to remain black is given a further treatment of a lubricant dressing, which consists of montan wax, paraffin wax and gilsonite. Wire that is to be colored for reasons of polarity is coated over the intermediate coat with a coloring solution which consists of an alcohol soluble gum, a pigment and a plasticizer, such as castor oil.

Even without additional facts it may be stated that several of the chemicals mentioned are quite capable of producing skin disorders. Contact with the rubber covered cotton braid may

lead to definite dermatitis if certain accelerators were used in connection with the curing of the rubber. In this situation patch tests should be used with the various portions of the wire insulation, particularly the rubber coated braid.

The entire situation with respect to dangers from wire coating material cannot be disposed of by pointing out that dermatitis may follow contact. In extensive use in this industry are a variety of chlorinated naphthalenes and chlorinated diphenyl. The disturbing "color acne" apparently is linked with the chlorination. In addition to injury to the skin, profound systemic disease may be produced under conditions of appropriate exposure in which the liver may be severely damaged. In some instances these insulating waxes may be dissolved in carbon tetrachloride, toluene or benzene. Obviously these substances possess toxic properties, and when their vapors are inhaled or when the skin is brought in contact with them disturbances may arise. The entire problem of the toxic properties of chlorinated hydrocarbons in connection with their use in the wire industry formed the basis of a symposium presented in part in the *Journal of Industrial Hygiene and Toxicology* 19:283 (Sept.) 1937 in a publication by Drinker and his associates. A separate publication based on this symposium has been prepared by the Harvard School of Public Health under date of June 30, 1937.

POSSIBLE INTESTINAL OBSTRUCTION FROM GUMMA

To the Editor:—A patient with complete obstruction for three days, a history of 25 pounds (11 Kg.) loss of weight, and constipation of a year and a half, was operated on. A hard hour glass constrictive mass completely obstructive in the descending colon was found, which was thought to be a cancer. There were no detectable metastases to other viscera. The operation consisted of cecostomy for relief of obstruction. Signs of syphilitic heart disease with signs of central nervous involvement, as evidenced by Argyll Robertson pupils, prompted the taking of a Kahn test, which was 4 plus in all dilutions. The patient has made a nice recovery and after two injections of a bismuth compound plus iodide has had normal bowel movements. I have been unable to find any parallel cases. If the mass is a gumma, is it reasonable to hope that antisyphilitic treatment will keep the lumen of the involved portion of the colon patent?

M.D., Texas.

ANSWER.—Syphilis of the large or small bowel is apparently rare; in fact, it is so rare that records of indisputable cases are not found in the literature, although reports of presumptive cases appear occasionally. A similar case (not reported) with rapid disappearance of the obstruction following two injections of arsphenamine and a positive Wassermann test of the blood as the only evidence on which to base the diagnosis of syphilis has been noted. A conclusive diagnosis of syphilis of the colon should be based on (1) x-ray demonstration of the mass in the bowel, (2) serologic or clinical evidence of syphilis, (3) pathologic changes characteristic of syphilis in tissue from the mass, (4) involution of the mass under antisyphilitic treatment and (5) observation for five years or more.

Experience would indicate that, if the constriction is due to a gumma, antisyphilitic treatment will keep the lumen open; if, in fact, obstruction recurs it would suggest that syphilis is not the cause of the bowel condition.

DERMATITIS FROM DRESS SHIELDS

To the Editor:—A patient has a dermatitis corresponding to the size of her dress shields. I should like to know how dress shields are made and what kind of chemicals are used in the manufacturing process.

M.D., Wisconsin.

ANSWER.—Dress shields are made of cloth impregnated with a rubber compound. This is covered by ordinary fabric. The cause of the dermatitis is probably the rubber, which is subjected during manufacture to the action of one of many forms of "accelerator." By the use of these the time needed for vulcanizing is reduced from hours to minutes. Most of the accelerators are chemicals and may be irritating to the skin or are among those substances to which the skin becomes sensitized easily. Aniline, paraphenylenediamine, thiocarbonyl, sulfur chlorides and hexamethylenetetramine (the familiar methenamine used as a urinary antiseptic) are some of the common ones. Methenamine gives off formaldehyde in an acid medium, which makes it valuable in the bladder when the urine is acid. Acid sweat in the axilla acts in the same way and formic acid is produced, which is an active irritant (Shepherd and Krall: Poisons in the Rubber Industry, *J. Indust. Hyg.* 2:33, 1920). The cloth covering of the dress shield is no protection when it is saturated with sweat. The rubber industry is trying to replace the more irritating accelerators with those less apt to cause trouble.

It may be possible to prevent the dermatitis in the case under discussion by the substitution of paper dress shields for the

ones made of rubber. The paper ones are pinned to the dress and discarded when they become soiled. Attempts to lessen axillary sweating are not advisable. A degree of suppression of axillary sweating sufficient to warrant discarding the dress shields cannot be obtained from the use of x-rays with safety, though excessive sweating can be lessened in this way.

TENDER NODULES AFTER INTRAMUSCULAR INJECTION

To the Editor:—A woman, aged 33, cannot take sedatives by mouth and she has an idiosyncrasy to opiates. The nurses gave her four capsules of soluble phenobarbital into the biceps muscles (two in each arm) over a period of forty-eight hours. The injections were given by several different nurses, who have often given the same drug. Several weeks later the patient reported that she had tender nodules at the site of each injection. On palpation there were deep, firm, slightly tender nodules. I felt that they would go away in time, and they are now less tender but are still present. Another physician has told her they will persist for life. What is the proper treatment, if any? What is the prognosis as to their disappearance? Is this a frequent enough happening to make one hesitate to use the drug?

M.D., New York.

ANSWER.—To answer the third question first, a completely soluble, nonirritating substance should be promptly absorbed from the muscle without unpleasant after-effects. Soluble phenobarbital is usually such a substance; therefore it is assumed that some complicating factor was present in this case.

Water solution of sodium phenobarbital is rather unstable and should be freshly prepared and injected at once lest irritating substances form in the solution. Rapid injection into the muscle and, indeed, slow injection in a person who bleeds easily may result in a small hematoma at the site of injection. The statement that the patient cannot take sedatives by mouth raises the question of a personal sensitiveness to the drug that might produce sufficient tissue reaction to cause the symptoms.

There is no specific treatment. The application of heat may hasten resolution but resolution takes place in any event. Such nodules usually completely disappear. In infrequent instances they may remain palpable for a long period of time but they become so small and insensitive that they are of no concern to the patient.

MUSCULAR DYSTROPHY

To the Editor:—A boy, aged 14, fell from a height of 15 feet at the age of 3, striking his spine just below the neck. Since then a progressive atrophy has developed of all the muscles of the body except the lower part of the legs, which have apparently remained normal. He is emaciated, with atrophy of all muscles and with little or no subcutaneous fat. The skin is dry, and the reflexes are absent with exception of the pupillary reflexes, which are normal in reaction to light and in accommodation. He walks with a peculiar swaying gait and has a marked lordosis. When he falls or lies flat he has a characteristic "climbing on himself" method of rising, suggesting pseudohypertrophic muscular dystrophy. There is no history of any similar condition in his immediate or distant family. Can you suggest a diagnosis and any type of treatment? Do you think aminoacetic acid and a high protein diet would be of value?

M.D., Pennsylvania.

ANSWER.—In spite of the fact that there is no family history, the description of the patient is such that muscular dystrophy is practically the only disease to be considered. As trauma appears to have no part in this disease, the history of the fall at the age of 3 should be disregarded. Neither aminoacetic acid nor a high protein diet has proved to be of any value in dystrophy. One or two patients have been somewhat relieved and perhaps made 5 or 10 per cent better by oral prostigmine. Before any treatment is considered, the diagnosis should be made certain by biopsy.

ADRENAL CORTEX IN HAY FEVER

To the Editor:—Will you kindly supply information concerning the treatment of hay fever by the use of adrenal cortex extract?

LOUIS W. GERSTNER, M.D., Kalamazoo, Mich.

ANSWER.—A review of the literature on the use of adrenal cortex extract is given in a paper by Prickman, Giles and Koelsche (*J. Allergy* 158:9 [Jan.] 1938). These workers administered the extract intravenously to nineteen patients, of whom sixteen had asthma, two severe vasomotor rhinitis and one severe urticaria and angioneurotic edema. They concluded that the treatment gave little or no specific benefit in these conditions. More favorable results on the use of the extract are reported by the Pottengers (*California & West. Med.* 43: 10 [July] 1935), who treated fifty asthmatic patients. The adrenal cortex extract in these cases was administered orally. Thirty of the fifty patients were greatly improved. It is noteworthy that a program of rest was required of each patient.

in addition to the medication. The reports of other workers who used the extract in allergic conditions are much less favorable than the report of the Pottengers. No reference has been found to the use of adrenal cortex extract in uncomplicated hay fever. Rappaport and Hecht (unpublished data), however, gave massive doses of adrenal cortex extract by mouth coseasonally to eighteen ragweed hay fever patients in 1935 with no noticeable benefit. It is questionable whether the material is at all effective orally.

EPHEDRINE TO PREVENT TRANSFUSION REACTIONS

To the Editor:—In the hope of preventing unfavorable reactions following a blood transfusion in an allergic patient, three-eighths grain (0.024 Gm.) of ephedrine was given by mouth and immediately following the transfusion of 500 cc. of whole blood, three-fourths grain (0.05 Gm.) of ephedrine hypodermically. No reaction was noted. Four days later another 500 cc. of whole blood was given and the ephedrine administered as before. Four hours later her temperature rose to 100 F. No other reactions were noted. Manifestly these two transfusions are of no statistical value. I am interested, however, to know whether ephedrine has been used in this way before and whether or not it has been found of value in the prevention or amelioration of undesirable reactions of transfusion of whole blood.

J. KINGSLEY MACDONALD, M.D., White Plains, N. Y.

ANSWER:—So far as is known, epinephrine and ephedrine have not been used in transfusions of human blood but when injecting serum, e. g., tetanus or diphtheria antitoxin, it should be used prophylactically if the skin or conjunctival tests for horse serum are positive, and therapeutically if serum sickness develops. The occurrence of serum reactions in man results usually from the introduction of a foreign or heterologous type of serum. It should not occur from injections of human serum, which is a homologous type. However, such reactions do rarely occur, and have been reported in the literature (Tuft, Louis: Clinical Allergy, Philadelphia, W. B. Saunders Company, 1937). The classic example is the case reported by M. A. Ramirez (Horse Asthma Following Blood Transfusion, *THE JOURNAL*, Sept. 27, 1919, p. 984), in which, following transfusion from a horse sensitive donor, the recipient developed a similar sensitivity on contact with horses. H. C. Berger (*M. Clin. North America* 7:1169 [Jan.] 1924) reported the occurrence of urticaria resulting from the injection of blood from a horse sensitive person into one who had previously received antistreptococcus and normal horse serum. Duke and Stofer (*ibid.*, p. 1255) reported a case of immediate serum reaction in a milk sensitive recipient whose transfusion was from a donor who had ingested milk. DeBesche (*Berl. klin. Wchnschr.* 46:1607, 1909) reported a case of sudden dyspnea following transfusion. Sensitivity from transfusion is temporary and disappears in a month or less. One cannot be permanently sensitized by blood transfusion or by any other method (except probably by inheritance). The Prausnitz-Küstner reaction (passive transfer) is an example of temporary local sensitivity of the skin which is frequently useful in determining the cause of attacks of allergic conditions.

DIET AND URIC ACID STONE

To the Editor:—Kindly outline the medical and dietary treatment of uric acid stone formation in the kidneys.

M.D., Alabama.

ANSWER:—To answer this question one would have to assume certain conditions: that the urine is not infected, that there is no obstructive uropathy, and that the size of the stone or stones is within the limits usually conceded as compatible with spontaneous passage (less than 1 cm. in diameter). Granted these premises, the question resolves itself into a discussion of purine metabolism and the control of uric acid excretion.

From 0.3 to 1.2 Gm. of uric acid is excreted in the urine daily, depending on the diet. This uric acid is either exogenous (from food) or endogenous (derived from the breakdown of body tissues). Purine bodies are formed from the nucleoprotein of highly cellular glands, such as thymus, liver or kidney, and extracts of muscular tissue; methyl purines are highly concentrated in tea, coffee and cocoa. Nucleoprotein is changed in the process of digestion into nucleic acid, which in turn is split into nucleotides. Each nucleotide is formed of phosphoric acid plus a carbohydrate, plus a nitrogenous base. Concerning the endogenous supply, even on a purine-free diet man will excrete from 0.3 to 0.6 Gm. of uric acid daily as the result of the breakdown of his cellular tissues. Only from 60 to 70 per cent of uric acid is eliminated in the urine; the rest is probably changed into urea. A definite explanation of the formation of uric acid kidney infarcts has not been given

but they are most probably due to a colloid imbalance in the urine. An acid urine may precipitate uric acid crystals.

True uric acid stones rarely demand treatment. They are usually precipitated as crystals which pass spontaneously, causing minor attacks of colic at the time. These patients pass small stones and gravel.

The diet may affect their course, but since even on starvation regimens the uric acid excretion is only about halved it must be realized that dietary treatment is in no sense curative. A purine-free diet would be too rigorous; the diet recommended is a good, mixed, easily digested one, avoiding only highly cellular organs, such as liver, sweetbreads, kidneys and brains. The bowels should be regulated with preferably a mild saline cathartic. Plenty of milk is recommended both because it is purine-free and because of its high vitamin content.

Since the formation of stones depends more on the concentration of a salt than on the total amount excreted in a day, the forcing of fluids is probably more efficient in the dietary treatment than reduction of purine-containing foods. The concentration can be as well controlled by doubling the fluid intake as by restricting the food.

In the presence of urinary infection, uric acid calculi quickly become coated with secondary salts. The problem is then much more complicated and dietary treatment is used not so much to control the size of the stone as to combat infection. The acid ash, high vitamin diet is extensively used in appropriate cases of this group.

In any stone, no matter what the composition, if it will not pass spontaneously, surgical treatment is necessary.

SEROLOGIC RELAPSE IN SYPHILIS

To the Editor:—A man, aged 37, has been treated for syphilis since February 1936. He was previously treated by another physician for about fourteen months with nearsphenamine and oleo-bi. The Wassermann reaction became negative. He was allowed a month's probation before returning for a Wassermann test. He did not return until six months had elapsed, when his Wassermann reaction was 4 plus. Since February 1936 he has had continuous overlapping treatment, starting with bismuth. This has consisted of two courses of nearsphenamine, ten and twelve doses respectively (0.6 Gm.) and four courses of mapharsen (0.06 Gm.) varying from ten to fourteen doses of thio-bismol, given at intervals of from three to four days. The Wassermann reaction was 4 plus for the first ten months of my treatment. It then became 1 plus, and the Kahn reaction became 1 plus Nov. 10, 1936. It remained so until September 16, when another laboratory (laboratory B) reported the Wassermann, Hinton and Kahn reactions negative. Again laboratory B reported all three negative, Dec. 10. Now (Feb. 28, 1938) laboratory A reports the blood Wassermann reaction 2 plus and the Kahn reaction negative, and laboratory C reports the Wassermann and Kahn reactions doubtfully positive (February 11). I have been unable to get the patient to submit to a spinal Wassermann test as yet, although I have tried to show him the dangers of untreated syphilis of the central nervous system. However, today he gave me his promise to have a spinal Wassermann test made in the near future. I realize that a neurorelapse may have occurred during the six months that he was untreated, thus accounting for the persistently positive reaction. What course should be pursued should the spinal fluid be negative? Should nearsphenamine and bismuth be continued in full doses until the blood Wassermann reaction is absolutely negative, or has a total of three years' treatment been sufficient for the present, without regard to the 2 plus or doubtful positive serologic reactions obtained recently? There are no signs or symptoms referable to the central nervous system or vascular system. In fact, the patient is in good condition. Should the spinal fluid be positive, I suppose the treatment should be directed toward the central nervous system, with trypanamide instead of nearsphenamine.

M.D., Pennsylvania.

ANSWER:—In the first place, the significance of the Wassermann relapse after the patient's fourteen months of treatment at the hands of another physician depends on what was wrong with the patient when his treatment started—whether he had early or late syphilis, which the inquirer does not state. If he had early syphilis there may have been, as stated, an opportunity for reinfection of his nervous system; if he had late syphilis, this is not the case. Whether he had early or late syphilis and if his spinal fluid is now completely negative, he has had enough treatment. The discrepancy between serologic results in laboratories A and B is certainly due to technical variation in the two laboratories and not to variation in the patient.

The spinal fluid examination should include cell count, quantitative estimation of the protein content, quantitative titration of the Wassermann test in amounts ranging from 0.1 to 1.0 cc., and colloidal mastic or gold curve.

If the spinal fluid is positive, the type of desirable treatment will depend on the ensemble of the spinal fluid picture. If the spinal fluid shows the paretic formula, treatment should be initiated with malaria to be followed by trypanamide.

VITAMIN AND MINERAL REQUIREMENTS
OF NORMAL DIET

To the Editor:—How can one tell whether a patient is getting sufficient mineral in his diet? Is it true that the average American gets more minerals and vitamins than he needs? How can one be sure that a patient taking no milk gets sufficient calcium?

M.D., Iowa.

ANSWER.—Since the availability of minerals differs according to the type of food, their source is an important consideration. Vegetables as a rule contain a less available form of calcium than does milk. Their iron is also probably not completely available. Sodium, potassium and magnesium, while required for health, are so plentifully distributed in foods that ordinarily they do not have to be considered in formulating dietary standards. The notion that the average American receives a greater supply of vitamins than he needs is not entirely compatible with the known facts. Exceptions must be made, for example, in the case of pregnant or lactating women. There is increasing evidence, however, that mild and frequently unrecognized deficiencies of some vitamins are more prevalent in this country than formerly was believed.

The "dietary standards," which are indications, not rules, are based on the minimum requirement for each substance plus an added 50 per cent, or in some cases 100 per cent, margin for safety. As expressed by H. C. Sherman (Chemistry of Food and Nutrition, ed. 5, New York, Macmillan Company, 1937, p. 520), for normal adults these standards are: calcium 0.68 Gm. (10 grains), phosphorus 1.3 Gm. (20 grains), iron 0.012 Gm. (0.185 grain). A discussion of the vitamin requirements appeared in *THE JOURNAL* Jan. 15, 1938, page 227.

TIME OF DEATH—BLEEDING AFTER DEATH

To the Editor:—1. When is a person judged to be dead, i. e., at what moment does death occur? 2. Would profuse bleeding from the ears and nose on one's arrival at the scene of an accident mean that a person was still alive? There are two people in the same automobile. One hour after the accident the coroner states that both are dead. The woman was bleeding profusely from the nose and ears one-half hour after the accident. 3. How long after death does one continue to bleed freely from a laceration or a skull fracture?

M.D., Indiana.

ANSWER.—1. Death has taken place when respiration and heart action have stopped permanently.

2. Yes, if the flow of blood continues longer than explainable by the running out, on change of position, of blood or bloody fluid accumulated in the ears and nose and adjacent parts. It is of course not possible that "profuse bleeding" from the nose and ears could go on continuously for half an hour after the heart has stopped beating. Is it excluded that what is called "bleeding profusely" may not have been due to the running out of the ears and nose of bloody cerebrospinal fluid?

3. With death the blood stops circulation; hence after death only the fluid blood in or about the parts involved can run out from a laceration or fracture. The amount of such "bleeding" will vary greatly in different cases and might well be influenced by change in the position of the body. To "bleed freely" in the usual sense is impossible after death.

ARTIFICIAL PRODUCTION OF URTICARIA
AND ALLERGY

To the Editor:—Is there any known way of producing urticaria in a normal person? Would it be possible by injecting some substances under the skin or by any other method to make a person sensitive with the result that urticaria would develop?

M.D., Minnesota.

ANSWER.—Urticaria can be artificially and temporarily produced in a normal person by any one of three methods: 1. It may be produced by the prophylactic or therapeutic injection of some form of animal serum, as horse serum (tetanic). A large percentage of persons who have had a manifestation known as "serum sickness"; urticaria is a prominent feature of this condition. 2. If an allergic donor gives blood for a transfusion, the nonallergic recipient may temporarily become hypersensitive to the antigen or antigens which caused the donor's symptoms; e. g., ragweed pollen, horse dander. Urticaria in the recipient may follow contact or ingestion of the offending substance. Fortunately such induced hypersensitivity is only temporary. Ramirez (Horse Asthma Following Blood Transfusion, *THE JOURNAL*, Sept. 27, 1919, p. 984) reported a case in which transfer of horse serum sensitivity followed the transfusion of a nonallergic recipient with blood obtained from a donor who had asthma from horse dander. This type of sensitization is rare in human beings. 3. In the classic method of testing by local passive transfer (Praisitz-Kustner reaction, *Centralbl. f. Bakt.* 86:160, 1921), blood is drawn from the allergic person and the serum is injected into the skin of a

normal person. About forty-eight hours later the injected site usually shows an itching wheal (urticarial reaction) when injected with antigens to which the donor is allergic. Other parts of the recipient's skin are usually negative to these antigens. Walzer (*J. Allergy* 1:231 [March] 1930) has also shown that these sensitized sites frequently develop urticarial wheals when an antigenic food, such as egg, is eaten. This local hypersensitivity likewise disappears in a few weeks. There is no known method by which a normal person can be made permanently hypersensitive so that he will show symptoms of urticaria, asthma or hay fever. Of course the "normal" person may not really be normal. He may, probably through inheritance, be potentially allergic; when his threshold of resistance has been exceeded, as by a large dish of crabmeat, urticaria may occur for the first time. It is known, however, that repeated exposure to certain weeds, such as primrose, can render most persons permanently hypersensitive; however, the symptoms produced are those of contact dermatitis (dermatitis venenata); the hereditary factor is absent in this condition.

GANGLION OF TOE

To the Editor:—A man, aged 30, about four months ago had an ingrown toenail on the right foot. I removed the lateral half of the nail. Removal was immediately followed by the flowing of a thick, colorless, gelatinous matter. He was relieved for two months, when he again returned with the same infected toe. I again performed a procaine block anesthesia and carried out the operation as described by Dr. R. W. Bartlett in *THE JOURNAL*, April 10, 1937, page 1257. The only tangible history obtainable is that about ten years ago he was playing football and hurt his toe, which became painful and swollen for a few days. About two years ago the toe became reddened and slightly swollen, again becoming normal with no ill effects. The swelling and redness recurred every few months or so until four months ago. Since operation a constant flow of this gelatinous material has been coming out of a sinus at the base of the nail leading down into the interphalangeal joint. What is the cause of this gelatinous material? What would be a proper diagnosis? Please outline a treatment. I have been treating the sinus with phenol; is this proper? Would it be advantageous to use a sclerosing agent?

M.D., Massachusetts.

ANSWER.—The clear gelatinous material discharged following operation on the toe is indicative of a ganglion, which may originate from the joint capsule or tendon sheath or of a bursa. Excision of the sac or bursa and the sinus tract is the desirable procedure. If this is not possible, thorough curettage of the sinus tract and the sac may lead to healing. Sclerosing solutions such as sodium morrhuate will at times lead to healing. If there is an opening into the joint, however, the use of a sclerosing solution is inadvisable because of the damage that may be done to the articular surfaces.

DERMATITIS FROM INVERT SUGAR FOR VARICOSE
VEIN INJECTIONS

To the Editor:—I am treating varicose veins on the lower extremity by injecting invert sugar. I used 10 cc. in the small veins on the dorsum of the foot and around the ankle, November 15; I used 10 cc. in the veins on the outer side of the leg, November 18. The patient came to the office November 21 with a dermatitis extending from the ankle to the upper third of the leg. The patient complained of severe burning and itching of the leg; there is also a slight dermatitis on both arms and on the sacral regions. Could this be due to the solution used?

M.D., Mississippi.

ANSWER.—Sensitization to drugs used for obliterating varicose veins is not uncommon; quinine, sodium morrhuate and potassium oleate are occasionally known to produce such reactions. However, it is difficult to conceive that a solution of invert sugar would produce sensitization unless one added some other ingredient, as an antiseptic or anesthetic, to the ampule. The solution might be tested for allergens with special reference to nitrogenous products, as impurities in the invert sugar. Such sensitizations may take the form of an itching dermatitis localized mainly to the injected areas or to the course of the vein; in other instances, a generalized urticaria develops and rarely an edema of the glottis with bronchial spasm.

ETIOLOGY OF INFLUENZA

To the Editor:—I recently received information that influenza is now known to be caused by a streptococcus. I did not know that the cause had been discovered. Is there now general agreement as to the causation?

M.D., Michigan.

ANSWER.—The evidence pertaining to a streptococcus as the cause of influenza is not generally accepted. Instead, a rather complete chain of evidence indicates that a filtrable virus is the primary causative agent of the disease. Isolated first by Smith, Andrewes and Laidlaw in London, England, in 1933, extensive studies have been conducted in this country by Francis

and his associates (THE JOURNAL, Aug. 21, 1937, p. 566). The virus has been recovered in a high percentage of cases of epidemic influenza, and the serums of the convalescent patients acquire a high titer of antibodies to the virus. The virus infects ferrets and mice and has also been shown after repeated passages in animals to be capable of inducing clinical influenza in man.

AIR SWALLOWING IN SMALL CHILD

To the Editor:—A boy aged 3½, intelligent and emotional, whose birth history is negative in every respect, cried severely during the first three months of his life and has already had eczema, measles, mumps and pneumonia. He had severe rachitis with an appearance of bony deformities. The parental history is not significant except that the father is highly emotional. The child is well nourished, of normal weight and height, somewhat active and somewhat pale, but development is normal. He has had "spells" once a month, beginning one year ago. The spells endure from five to six minutes and vary from two to twenty in a day, the average number being five or six. The spells are described as follows: He begins swallowing rapidly and audibly; this is followed by peculiar noises in the stomach and complaint of stomach ache, ending in the expulsion of flatus by rectum and his assertion "All better now."

M.D., Saskatchewan.

ANSWER.—The spells described are known as aerophagia, which is a spasmodic swallowing of air followed by eructation or flatulence and is often a symptom of hysteria. This condition may be classified under the functional coordination neuroses. It is stated that the boy is intelligent and emotional and that the father is highly emotional and that the spells occur once a month. This periodic occurrence is probably associated with periods of emotional stress. A sociologic investigation of the family life might throw considerable light on the causation of these spells.

POSSIBLE MONILIA INFECTION OF VAGINA

To the Editor:—The vaginal exudate from a pregnant patient almost at full term is very thick and has somewhat the appearance of necrotic tissue. There is little odor, and removing it from the membrane leaves a bright pink surface but no ulceration. This material has been removed from the vagina a number of times during the past few months. Stained smears show a large fungus occurring in broken up rods and staining poorly with methylene blue. There is no differential reaction with the Gram stain, there is a large amount of necrotic material and there are few pus cells. Cultures on Sabouraud medium show a growth and some brownish pigment production. However, I am unable to determine the type of fungus. What treatment is indicated? What type of fungus is responsible?

M.D., Georgia.

ANSWER.—The clinical picture is that of Monilia infection, although the evidence is insufficient for a certain diagnosis. There is no specific therapy. Mechanical cleansing of the surfaces and applications of 1 per cent gentian violet will probably effect a cure.

MEDICAL TREATMENT OF CANCER

To the Editor:—Two articles on cancer research have recently appeared in the press. One, concerned with oral administration of some substance in human beings, reported approximately 60 per cent cures; the other concerned the use of spleen extract in animals. Is authentic information available on the treatment or cure of cancer? My wife is now being treated for scirrhus carcinoma by x-rays.

M.D., California.

ANSWER.—The only accepted methods in the treatment of cancer today are by surgery, x-rays and radium. Any claim that the oral administration of some substance has resulted in the cure of human cancer in 60 per cent of the cases is totally without foundation. Spleen extract has been tried in the treatment of cancer in animals and man without success. Authentic information on the treatment and cure of cancer exists in the medical literature.

ANTITYPHOID SERUMS—MISTRETTA SERUMS

To the Editor:—In an article by Biagio Mistretta (*Policlinico* 44:2287 [Nov. 29] 1937) mention is made of the use of intravenous or intramuscular injections of 2 per cent phenolized artificial serum for the treatment of various infectious diseases. Can you inform me whether this method has been used in this country and the phenolized serum is available commercially? Will you also inform me whether the serum for typhoid discussed by C. J. McSweeney in the Dec. 4, 1937, issue of the *British Medical Journal* is commercially available in America?

HAROLD J. HARRIS, M.D., Westport, N. Y.

ANSWER.—The use of intramuscular injections of convalescent serum for the treatment of diseases is common, but we do not know of any reports from this country concerning the method described by Biagio Mistretta. Antityphoid serums are not now commercially available here.

TRICHLOROACETIC ACID CAUTERY IN EYE

To the Editor:—Can you give information concerning trichloroacetic acid in pencil form used for cauterizing in eye work? Who makes it and where can it be produced?

D. W. BRICKLEY, M.D., Marion, Ohio.

ANSWER.—We have no information on pencils of trichloroacetic acid. A tightly wound cotton applicator on a tooth pick dipped in the solution of trichloroacetic acid may be used and the area of prolapsed iris carefully touched so that no excess of solution is used and that none touches the cornea. It is unnecessary to neutralize the acid. The iris becomes gray-white immediately after the drug has been applied. The surrounding conjunctiva becomes red the next day and the iris is again black. This must be repeated several times. It may be used daily for ten days in some cases and three times a week for three weeks in others. The treatment should be used only in small prolapses in which there is no danger of the solution entering the anterior chamber.

TREATMENT OF HODGKIN'S DISEASE

To the Editor:—Is there any treatment for Hodgkin's disease other than with x-rays and arsenic? In my patient the process has extended into the mediastinum and abdomen.

W. C. PERRY, M.D., Louisburg, N. C.

ANSWER.—There is no successful treatment for Hodgkin's disease. X-rays or radium properly applied contribute to the patient's comfort and may perhaps lengthen his life, although the latter is questionable. Arsenic is thought to have a beneficial effect on the size of the glands. Various emulsions and other preparations have been used in the form of vaccine therapy but without proved benefit.

INCOMPATIBILITY OF EPHEDRINE AND IODINE

To the Editor:—What is the incompatibility between iodine and ephedrine compounds? One manufacturer of an iodine solution states on the label of his package, "Incompatible with ephedrine and ephedrine compounds."

FRANCIS BURTON BLACKMAR, M.D., Columbus, Ga.

ANSWER.—The statement that iodine is incompatible with ephedrine and ephedrine compounds is correct. When ephedrine hydrochloride in aqueous solution is mixed with either the tincture of iodine or the compound solution of iodine, a precipitate results that is soluble in alcohol. When to ephedrine alkaloid in alcoholic solution is added either the tincture of iodine or the compound solution of iodine, the liquid remains clear but gradually becomes decolorized on standing, as happens with iodine in other alkaline solutions.

SPLIT FINGER NAILS

To the Editor:—In THE JOURNAL May 19, 1928, was an article by W. W. Carter on split finger nails. His method of treatment by the use of sutures through holes drilled in the finger nail appears excellent. However, I suffered from this trouble and the method described did not seem satisfactory to me because I had to scrub my hands frequently. I did not like the idea of the holes or the roughness of the knots. I feared for the surgical cleanliness of my hands, not only on account of the uncertainty of the thoroughness of the mechanical cleansing but also because of the ease with which these recesses could become contaminated and probably hold foreign material. Finally I arrived at the following procedure, which has given good results: Celluloid dissolved in amyl acetate was painted on the thumb nail. Several coats were applied, each coat being allowed to dry before the succeeding coats were applied. One treatment will last for two or three weeks as a rule. A convenient and cheap source of celluloid is old unbreakable watch crystals which the jeweler is ready to discard. One small crystal dissolved in about 20 cc. of amyl acetate makes a solution of about the right consistency.

S. M. MACLEAN, M.D., Tacoma, Wash.

HIGH HUMAN TEMPERATURE

To the Editor:—The subject of high human temperature is discussed in *Queries and Minor Notes* in THE JOURNAL, February 5, page 461, and April 2, page 1127. Regarding the highest temperature that the human body can reach and still survive, the following (taken from Reid, W. D.: One Hundred and Fifty-Eight Cases of Heat Prostration Treated at the Boston City Hospital, July 2-13, 1911, *Boston M. & S. J.* 165:643 [Oct. 26] 1911) may be of interest:

Temperature	Cases	Deaths
—105	10	1
105—106	8	4
106—107	8	5
107—108	6	6
108—109	14	10
109—110	15	12

The high mortality, 58 per cent, in these cases of heat stroke was doubtless influenced by the complications: At admission to the hospital: alcoholism, failing heart, edema of the lungs and convulsions. Subsequent: delirium tremens, persistent coma, pneumonia and recurrence of fever.

WILLIAM D. REID, M.D., Boston.

Medical Examinations and Licensure

COMING EXAMINATIONS STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *THE JOURNAL*, May 14, page 1697.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, June 20-22 and Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral examinations for Group A and B applicants will be held at San Francisco, June 13-14. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examination will be held at various centers of the United States and Canada, Oct. 17. Final date for filing applications is Sept. 1. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Suite 1210, Des Moines, Iowa.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral, clinical and pathological examinations for all candidates (Groups A and B) will be conducted in San Francisco, June 13-14. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: San Francisco, June 13; Washington, D. C., Oct. 8; Oklahoma City, Nov. 15. All applications should be filed immediately and case reports, in duplicate, must be filed not later than sixty days before the date of examination. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Chicago, June 10-11. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: San Francisco, June 10-11. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: San Francisco, June 13-14. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec. Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: San Francisco, June 11. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: San Francisco, June 10-12. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Examination for candidates living along the northeastern and southeastern seaboard and western part of the United States, latter part of May. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: San Francisco, June 11-13. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

District of Columbia January Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports the written examination held at Washington, Jan. 10-11, 1938. The examination covered 9 subjects and included 60 questions. An average of 75 per cent was required to pass. Eight candidates were examined, all of whom passed. Nine physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine....	(1936)		81.3,
83.8, 84.6, 87.8, 90.3			
Georgetown University School of Medicine.....	(1936)		86.3
Long Island College of Medicine.....	(1936)		83.8
Temple University School of Medicine.....	(1935)		78.5

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
George Washington Univ. School of Medicine (1935),	(1936) N. B. M. Ex.		
Georgetown Univ. School of Med., (1934), (1935),	(1936, 3) N. B. M. Ex.		
University of Louisville School of Medicine.....	(1934) N. B. M. Ex.		
Duke University School of Medicine.....	(1935) N. B. M. Ex.		

Hawaii January Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, reports the oral and written examination held at Honolulu, Jan. 10-13, 1938. The examination covered 10 subjects and included 80 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Two physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of California Medical School.....	(1935)		84.8
Loyola University School of Medicine.....	(1936)		78.2
School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
College of Medical Evangelists.....	(1935) N. B. M. Ex.		
University of Pennsylvania School of Medicine.....	(1935) N. B. M. Ex.		

Book Notices

Surgical Diseases of the Mouth and Jaws. By Earl Calvin Padgett, B.S., M.D., F.A.C.S., Associate Professor of Clinical Surgery, University of Kansas School of Medicine, Kansas City, Kansas. Cloth. Price, \$10. Pp. 807, with 334 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

The material of this book covers a much broader field than the title would indicate. Medical diseases and some surgical conditions of the pharynx, larynx, esophagus and neck, as well as plastic surgery of the face, are included. These subjects would not be looked for in a book with this title. Dr. Padgett has attempted, as he states in his preface, to cause his book to appeal to the dental student, the medical student, the dentist, the physician, the surgeon, the nose and throat specialist, the dermatologist and the radiologist. Although this is a difficult task, as is evident from the arrangement of the book, it well reflects the breadth of the author's interests as teacher and surgeon. The author stresses the value of a broad knowledge of gross and microscopic pathology. The book is well illustrated with diagrams, photographs of patients, roentgenograms and photomicrographs. The chapters on plastic surgery are excellent, particularly the chapter on congenital deformities; they are indicative of wide experience in this field. The student will find this book a very careful review of the literature and an excellent summary of the material under discussion. Some surgeons would like to read, in subsequent editions, more material springing from the author's own considerable surgical experience.

Mentality and Homosexuality. By Samuel Kahn, B.S., M.A., M.D., Associate Attending Neurologist at the City Hospital and Central Neurological Hospital, New York. Cloth. Price, \$3. Pp. 249. Boston: Meador Publishing Company, 1937.

This small book gives a perfectly clear and accurate description of the homosexuals interviewed and studied by the author in the prisons at Blackwell's Island, New York. One is struck not only with the clarity of description but with the honesty of the writer, who puts things down exactly as he saw them without any particular theory to promulgate. The book will be a welcome addition to the libraries of those who take a psychoanalytic view of homosexuality. Those, however, who take the stand that homosexuality is, in the largest number of cases, due to endocrine influences and to the hormones poured into the system by the sex organs of the individual will have much to criticize in this work. Like all psychoanalysts, the author hardly makes any mention of the sex organs as the cause of the condition except in a slight reference that the endocrine system among others should be investigated.

The author in his accurate description of the homosexual brings out the fact that, aside from the particular anomaly, the homosexual differs little from other people, that he has the same vices, the same virtues as the rest of mankind and that his anomaly does not prevent him from becoming a great genius. The author also brings out the fact that the homosexual does not consider himself a degenerate but that in reality (and this is distinctly contrary to psychoanalytic conception) his loves and attractions are distinctly in accord with his endocrine reactions. When one considers that in animals the sex attractions and desires can be changed by the investigators simply by removing the sex organs of the animal and substituting those of the opposite sex, without any change in the environment of the animal, the cause of homosexuality in the human race can be easily understood by comparison and inference. When at autopsy or at operation in some of these human homosexuals one finds sex organs of the opposite sex in the body, and also when one finds in some of these homosexuals that the ratio between the male and the female sex hormones in the blood is disturbed, one need not look for environment or infantile accidents as a cause of the condition but conclude that it is the endocrine hormones which in the majority of cases are the cause of the abnormality.

Although the author is a psychoanalyst and views everything from the standpoint of psychoanalysis, his own accurate description of the homosexuals would constitute the greatest argument in favor of the endocrine rather than the psychoanalytic

conception of homosexuality. He states as a fact that most of the male homosexuals are uncircumcised. This is exactly in line with what most observers in this field have brought out, namely, that the Jews as a race have few homosexuals. Now, were the psychoanalytic conception of homosexuality correct, this race in particular should be full of homosexuals. The poorer members of this race with their proverbial large families have been living in the poorest and cheapest tenement houses, often a family of eight or more members living in three or four rooms, where it is practically impossible to keep the sexes apart in childhood and even in adolescence. When one considers also that for centuries this race has been cooped in ghettos all over the world, also living in small and inadequate quarters, were the psychoanalytic origin of homosexuality correct, namely, that in some of the cases the condition is due to a child seeing the sex organs of the opposite sex, one would again naturally expect a large amount of hereditary homosexuality in this race and yet the very reverse is the fact.

The author states that the treatment of homosexuality is really so complex that volumes can be suggested, and yet no definite results can be promised. He further states that he does not believe that a reliable prognosis can be given with regard to active homosexuality. This is in line with the observations of other authors who treat the condition on psychoanalytic lines, some of whom have definitely stated that they have never cured a case of homosexuality. In view therefore of their own honest conclusions and statements of fact, one can wonder why the psychoanalyst should persist in his theory when he admits that treatment according to this theory is practically never successful.

The book gives much clear and distinct information about homosexuals in prison life, information which cannot be obtained from any other source.

The Dissection and Study of the Sheep's Brain as an Introduction to the Study of the Human Brain. By James Wilkie, B.Sc., Department of Biology, Guy's Hospital Medical School. Foreword by Professor T. B. Johnston, Guy's Hospital Medical School. Cloth. Price, \$2.25. Pp. 95, with 53 illustrations. New York & London: Oxford University Press, 1937.

This little manual will be gratefully received by all students of comparative mammalian neuroanatomy and all medical students who begin their study of the gross anatomy of the brain with the brain of a sheep. The book is clearly and simply written. In fact it at times descends to a juvenile level somewhat beneath that of the students for whom it is intended. The text presents a carelessness with the English language, a colloquialism, not anticipated in a book from this source. For instance, the author uses "pia" for pia mater, "medulla" for medulla oblongata, "cranial" for cranial nerve, "pituitary" for pituitary body, and so on. "In front" and "behind" are used to mean ventral and dorsal as well as cephalad and caudad, at times in the same or neighboring paragraphs and to the confusion of the reader. The illustrations, pen and ink drawings by the author, are very good. Two minor errors are noted in them. In figure 2 the sixth cranial nerve is not identified and in figure 42 "inf. cap" is used where int. cap. is intended.

Pulmonary Tuberculosis in Practice: A Modern Conception. By R. C. Wingfield, B.A., M.B., B.Ch., Medical Superintendent, Brompton Hospital Sanatorium, Frimley. Cloth. Price, \$2.50. Pp. 122, with 25 illustrations. Baltimore: William Wood & Company, 1937.

Wingfield divides tuberculosis into its various phases of development from the time the tuberculin test first becomes positive to the advanced stage of the disease. The various steps are illustrated graphically in one large chart. He states that the student in medical school "learns next to nothing about his main tasks, namely, the detection of the disease in its treatable stages and the supervision of his successfully treated cases." As "present-day teaching and present-day textbooks show him the moderately advanced case during its symptom-producing active stage and almost totally ignore the vitally important earlier half of the development of the disease both in its clinical and pathological aspects," the book was prepared to provide a comprehensive and logical picture of the pathogenesis of chronic pulmonary tuberculosis, as well as the methods of treatment appropriate for each stage of the disease. Attention is called to the fact that our knowledge of the partial active immunity

produced by the primary infection is, indeed, scanty and that we have no method of measuring such immunity. Under the discussion of diagnosis, emphasis is placed on the fact that the disease in its reinfection form in nearly every case establishes itself without causing symptoms of sufficient gravity to alarm its victim. With reference to the use of the x-rays in diagnosis he says "It is to be hoped the day will come when the x-ray will be as freely used as the clinical thermometer," although he points out that a roentgenogram "simply demonstrates that there is an infiltration of the lung but tells very little as to the character or the cause of the infiltration; it may be nontuberculous." He emphasizes the extreme importance of assembling information from all phases of an examination before arriving at a final diagnosis. Under treatment all procedures are discussed from strict rest in bed through the various forms of collapse therapy. Complications, such as hemorrhage, pleural effusion, spontaneous pneumothorax and tuberculous laryngitis, are given adequate consideration. Throughout the book Wingfield emphasizes the great importance of the general practitioner in the diagnosis, treatment and prevention of the disease. This book is sufficiently comprehensive as to be of value to all physicians engaged in the diagnosis and treatment of tuberculosis.

Involutive und idiopathische Angstdepression in Klinik und Erbllichkeit. Von Dozent Dr. K. Leonhard, Oberarzt der Nervenkl. in Frankfurt a. M. Boards. Price, 7 marks. Pp. 116, with one illustration. Leipzig: Georg Thieme, 1937.

The author presents his investigations of the nosologic and idiopathic features of forty-two cases of anxiety and agitated psychoses, chiefly depressions, in both men and women. His conception is a modification of the classification of Kraepelin, which separated the involuntional melancholias from the manic-depressive cases. Leonhard concludes from a study of his material that there are periodic anxiety and agitated depressions occurring in younger persons, which are "idiopathic" and should not be included among the manic-depressive group. He finds a strong hereditary basis for these psychoses and considers them identical with the more typical involuntional agitated depressions, because of their symptomatologic and hereditary similarities. The case material is presented with a brief clinical description of each psychotic episode and a brief description of psychopathic members of the family. The discussion concerns itself exclusively with phenomenologic and hereditary data, completely disregarding the personality, experiential and biographic features and their dynamic implications. The finding of a familial incidence in the affective psychoses is well recognized and throws no real light on their etiology or pathogenesis. It is felt, therefore, that this book has little to recommend itself to the American psychiatrist.

Concepts and Problems of Psychotherapy. By Leland E. Hinsie, M.D., Professor of Clinical Psychiatry, College of Physicians and Surgeons, Columbia University. Cloth. Price, \$2.75. Pp. 199. New York: Columbia University Press, 1937.

There has been a need for some time for a comprehensive book that would cover the use of psychotherapy by physicians. Hinsie has attempted somewhat to make such a volume for the use of the individual who is devoting his life to mental treatment. Unfortunately he falls short of his goal. It is quite true that a young psychiatrist beginning his work in this field would be interested in knowing something about the various types of psychotherapeutics which are in use today. He undoubtedly would want more than just a description of procedures and would want an idea of precisely how they are used, by whom they should be used, and, if they are not easily translated from the printed words to action, how they can be learned. Unfortunately, however, all that Hinsie's book contains is a brief summary of the more conventional freudian ideas, supplemented with chapters devoted, first, to Adolph Meyer's psychobiology and, secondly, to the work of Adler and Jung. In none of these chapters is anything new presented. Many of the recent books on psychoanalysis which are written by reputable authorities, such as Kubie's, will give a better picture of this field than has Hinsie. One gets the idea from his description of Adolph Meyer's psychobiology that he does not fully understand what Meyer is driving at and that the principles as enunciated by the doyen of American psychiatrists have

been mastered only in terminology and that their actual application and an understanding of them is not here thoroughly demonstrated by the author. As for Adler and Jung, one would naturally expect to find a tendency to minimize the contributions of these individuals. This, of course, is due to the fact that Hinsie's basic training is primarily along the lines of Freudian psychoanalysis. More interesting perhaps than Hinsie's own work is a supplement by Carney Landis showing statistically the way in which treatment is being used in mental hospitals today. This presentation is dramatic, interesting and one that should be taken from its setting in the present volume and presented individually. Hinsie does, however, offer a conclusion which is interesting and encouraging along the lines of the adoption of psychotherapy to active treatment work with mental cases. The book closes with a satisfactory bibliography.

Die Bluttransfusion als Mittel zur therapeutischen Umstimmung. Von Prof. Dr. Rudolf Stahl, leitender Arzt der Inn. Abteilung des Krankenhauses Bethanien, Breslau. Veröffentlicht von der Schlesischen Gesellschaft für vaterländische Cultur. Paper. Pp. 36, with 21 illustrations. Breslau: Ferdinand Hirt, 1937.

This brochure emphasizes the after-effects obtainable from blood transfusion, which are likened to parenteral alterative influence (umstimmungs therapie). Immediately following the transfusion there is a biphasic tendency: phase I with rising temperature, sympathicotonia, increase in blood calcium, tendency to acidosis and a leukocytosis change in the direction of myeloid character, with increased basal metabolism and blood sugar. The second phase is characterized by the opposite tendencies: falling temperature, vagotonia, increased potassium in blood and alkalosis, lymphocytic increase and diminution in basal metabolism and the sugar content of the blood. This, however, is not the end of the changes, because the author has been able to detect protracted excitation processes which may reach their height between the fifth and fourteenth days after the transfusion and last as long as from three to four weeks. This shows itself especially in a secondary increase in erythrocytes, frequently with the appearance of reticulocytes. There is also an increase in the antibacterial agglutinin titer. He therefore advises blood transfusion not only for restorative purposes in anemia but also for the hemostatic value as well as for the purpose of stimulating the reparative functions of the system. He considers such stimulation particularly valuable in peptic ulcers and in cases of ulcerative colitis that have led through bleeding to secondary anemia, but he considers these of value even in cases in which anemia is not marked. In sepsis suitable blood transfusions may be life saving. He prefers direct transfusion by means of Percy's paraffin cylinders most especially in infectious diseases, but he considers indirect transfusion or transfusion of preserved blood as being worthy of trial. He deplors, however, anything that tends to lessen the glamour that surrounds the transfusion of blood from man to man.

Artificial Fever Produced by Physical Means: Its Development and Application. By Clarence A. Neymann, A.B., M.D., F.R.S.M., Associate Professor of Psychiatry, Northwestern University Medical School, Chicago. Cloth. Price, \$6. Pp. 294, with 68 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1938.

This is a careful study of the various methods of production of fever therapy by physical means which describes the basic principles, history, physiology and technic of application of fever therapy for various diseases, particularly dementia paralytica, syphilis of the central nervous system, primary and secondary syphilis, multiple sclerosis, chorea minor, arthritis, gonorrhea and asthma. The author seems to lay undue stress on the value of producing fever by means of electromagnetic induction and seems somewhat biased in favor of this method. Nevertheless he does give careful descriptions of other methods of treatment. He is a mite too concerned about his own priority in certain phases of this investigation and a bit too prone to the use of the first personal pronoun. One may be startled by the recommendation that if the patient's temperature becomes too high he should be bathed with ice water. It is generally felt that tepid sponges and fanning of the nude body will produce much more rapid drop in temperature, whereas applications of ice water tend to constrict the peripheral capillaries and prevent the radiation of heat. Aside from these minor criticisms, the book

can be recommended highly as a careful, workmanlike, scientific contribution by an author who is justly enthusiastic about the results to be obtained with this fairly new therapeutic procedure. The work is exhaustive, and an excellent bibliography is attached. The book can be recommended to all physicians interested in fever therapy and in the various diseases which are amenable to this procedure.

Dixon's Manual of Human Osteology. Revised by E. R. Jamieson, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh. Second edition. Cloth. Price, \$7.50. Pp. 465, with 180 illustrations. New York & London: Oxford University Press, 1937.

The first edition of this book was published in 1912 by Prof. A. Francis Dixon of Trinity College. It was written for junior students who began their study of gross anatomy with osteology. The second edition has been rewritten by Dr. E. B. Jamieson of Edinburgh for the same students and with the same purpose. It is half as big again as was the first edition (465 pages as against 301) because Dr. Jamieson has found it advisable to include an account of many of the soft parts associated with the bones. So much material of this kind has been introduced that this edition might well be called an introduction to practical gross anatomy. He has added also an account of the development of bone and devoted more attention to joints and to the movements of joints. The illustrations are for the most part the excellent ones that appeared in Dixon's first edition; Dr. Jamieson has, however, substituted for some of them illustrations taken from Cunningham's *Practical Anatomy* and has added a few. The account of the development of bone being intended for junior students is a plain statement of the generally accepted views. Controversial opinions are omitted. No mention is made of Policard's views of the function of osteoclasts and osteoblasts. The teleologic idea that structures and processes are adapted in advance to demands which appear very much later is accepted without question. Students who have time to make a special study of bone before beginning dissection of the human body will find this book of great help in carrying on such studies.

Handbuch der experimentellen Pharmakologie. Begründet von A. Heffter. Ergänzungswerk. Herausgegeben von W. Heubner, Professor der Pharmakologie an der Universität Berlin, und J. Schüller, Professor der Pharmakologie an der Universität Köln. Band V: Enthaltend Beiträge von H. Schlossberger, et al. Paper. Price, 39.60 marks. Pp. 307, with 24 illustrations. Berlin: Julius Springer, 1937.

Heffter's handbuch is the most extensive and complete work on pharmacology. Additions to it are indispensable in research libraries. The present volume deals with chaulmoogra oil and its allies by Prof. H. Schlossberger of Berlin, coramin and metrazol by Prof. Fritz Hildebrandt of Giessen, the harmine group of alkaloids by Prof. J. A. Gunn of Oxford, and insulin by Profs. E. M. K. Geiling of Chicago, H. Jensen of Baltimore and G. E. Farrar of Philadelphia. The history, pharmacology and extensive literature of these drugs are given. Chaulmoogra oil has been used in Hindu medicine for a thousand years. One might therefore expect an extensive ancient literature. However, until 1854 its use in leprosy was not generally recognized, and not until 1904 was the attention of the scientific world drawn to it. One hundred and twenty-seven pages are devoted principally to its chemistry and pharmacology. Pyridine-beta-carbonic acid diethylamine (coramin) is a medullary stimulant resembling in action camphor, nicotine and metrazol. Its value in medicine has not been established. The discussion of its pharmacology occupies thirty-two pages. Pentamethylenetetrazol (metrazol) was first prepared in 1924. It is extensively used at present in the treatment of psychosis and is of vital interest. Its action is somewhat similar to that of picrotoxin, a medullary stimulant. Its pharmacology is given in thirty-two pages. Its therapeutic use is not described. The harmine group of alkaloids is described in English. The plant from which these alkaloids are obtained is indigenous to southern Russia, the Balkans and the eastern Mediterranean countries as far as Tibet. Among other actions, it dilates the coronary vessels and has a quinine-like action on the uterus, but no therapeutic use of these actions is suggested. Insulin is also described in English. The discussion is extensive and complete (eighty-three pages). One can do justice to it only by saying that it is perhaps the best monograph

graph on the subject of insulin. Heffter's handbuch is primarily for research workers. The present volume, however, will be found valuable for clinicians interested in the uses of chaulmoogra oil, metrazol or insulin. Unlike most of the earlier volumes, this one contains both subject and author indexes, which add greatly to its value.

A Method of Anatomy: Descriptive and Deductive. By J. C. Boileau Grant, M.C., M.B., Ch.B., Professor of Anatomy in the University of Toronto. Cloth. Price, \$6. Pp. 650, with 564 illustrations. Baltimore: William Wood & Company, 1937.

This is a short textbook in anatomy, evidently intended for use with dissecting manuals and atlases. The method to which the title refers is one by which the author seeks to give the medical student a less formidable textbook than the books commonly used; the latter are discouragingly large and their arrangement is systematic, that is, by systems—bones, muscles, arteries and nerves; the arrangement of this book is regional. Many attempts to give shorter anatomies to medical students have been made and most have failed. The student found them insufficient either for his own interest or for examinations, and though the standard textbooks were long, they were attractive, logically arranged and beautifully illustrated. So students preferred them, doing their own selecting and possessing a comprehensive work for lifelong reference. But the time devoted to dissection in the medical curriculum is much less than it was thirty years ago and many students would welcome a really good, practical introductory work that would be enough for the first examinations in anatomy. This book is the best of its kind that has appeared. It is probably adequate for medical, that is, clinical, anatomy. The material is presented logically and made somewhat easier to remember by skilfully worded correlations. It is evident that it was written by an experienced, conscientious and successful teacher. It would be of still more service to students if it contained directions for dissection, with lists of structures exposed at each stage. It does not include surface anatomy or the anatomy of the brain. A few mistakes are perhaps inevitable in a first edition, being corrected in later ones; for example, in terms, as rectovesical for recto-uterine on page 143, or of fact, as the statement on page 132 that the longitudinal muscle does not form a complete cover for the large intestine. The illustrations are for the most part original diagrams which the student can advantageously reproduce; he would depend on the excellent atlases now available for more elaborate illustrations.

Bentley and Driver's Text-Book of Pharmaceutical Chemistry. Revised by John Edmund Driver, Ph.D., M.Sc., F.I.C., Lecturer on Chemistry in the University College of Nottingham. Third edition. Cloth. Price, \$7.50. Pp. 624, with 48 illustrations. New York & London: Oxford University Press, 1937.

This is a textbook for students and the arrangement is logical. The inorganic portion follows the periodic system so far as practicable, and the organic portion follows the classification generally accepted by organic chemists. Since this is intended to cover a laboratory course, it would make an excellent laboratory manual. The methods used are, as a rule, chosen for simplicity and economy. The use of a Duboscq colorimeter is not mentioned, but colorimetric determinations are made with perforated blocks of wood containing test tubes of colored substances or by the use of Nessler tubes. Gas analysis is made in Hempel burets. The use of melting point apparatus, pycnometers, viscosimeters, refractometers and polarimeters is described. The colored chart of Clark and Lub's indicators, together with methyl orange, cochineal and litmus, is given. The tests for heavy metals might be applied to biochemistry after the destruction of organic matter. In the detection of organic compounds, usually a number of tests are given (and since most of these are not absolutely specific, the confirmation by a number of different tests is often desirable). The later chapters contain many substances of special physiologic interest and they are treated usually in a theoretic manner without laboratory methods being given for their estimation. It is hardly probable that this book would replace Autenrieth and Warren's Detection of Poisons for the research worker. The most important alkaloidal precipitating agents are not mentioned and no adsorption methods of isolating alkaloids are given.

The Role of Chemiotaxis in Bone Growth. By A. P. Bertwistle, M.B., Ch.B., F.R.C.S. Cloth. Price, 8s. 6d. Pp. 59, with 32 illustrations. London: Henry Kimpton, 1937.

The author states that the object of the book is to describe disruptive chemotaxis, indicating the power of certain hard substances to draw into them certain soft lining substances and to lay down a law "that whenever young fibrous tissue, particularly young blood vessels, come into contact with bone or a calcified deposit new bone formation occurs." Bone development is concisely reviewed. It is asserted that in the process of ossification calcium is always laid down first; then young fibrous tissue grows in and forms bone. This is true however only for enchondral ossification, so that the author is faced with the necessity of finding another explanation for intramembranous or fibrous ossification. A discussion of pathologic processes of ossification follows, but it is difficult to see wherein the author contributes anything more than a new phrase in his attempt to shed new light on the biophysical and biochemical processes of ossification.

Atlas of Skeletal Maturation. By T. Wingate Todd, M.B., Ch.B., F.R.C.S., Henry Willson Payne Professor of Anatomy, Western Reserve University, Cleveland, Ohio. With the collaboration of colleagues and assistants, 1926-1936. Cloth. Price, \$7.50. Pp. 203, with 75 illustrations. St. Louis: C. V. Mosby Company, 1937.

The author and his collaborators have studied skeletal maturation by means of serial roentgenograms of a large number of selected males and females at frequent intervals throughout the growth period. Standard observations have been set up at three or six months intervals from three months after birth to 16 years in girls and 19 years in boys, at which dates maturity is reached. Forty standard roentgenograms of the hand of the male and thirty-five of the female covering the period of maturation are reproduced and the changes recorded with great precision. Maturation is observed to proceed more rapidly in the female throughout the entire period but more noticeably after the first year. This is a masterly study of skeletal growth and it is to be hoped that the author will publish similar studies which he indicates he has made of the rest of the skeleton.

Voprosy obshchey i chastnoy rentgenologii. Trudy Gosudarstvennogo Ordena Lenina Instituta Usovshenshtvovaniya Vrachey im S. M. Kirova, Kafedra rentgenologii, Tom vtoroy. Pod obshchey redaktsiyei B. E. Rozina. Otvetsvennyy redaktor S. A. Reynberg. [Problems of General and Special Roentgenology. Works of State Order of Lenin Institute for Training of Physicians, named after S. M. Kirov, Department of Roentgenology, Volume II.] Cloth. Price, 15 rubles. Pp. 296, with illustrations. Moscow & Leningrad: Izdatelstvo Akademii Nauk SSSR, 1937.

This, the second volume issued by the chair of roentgenology of the Kirov Postgraduate Institute in Leningrad, is a collection of papers dealing predominantly with problems of experimental character. The subjects investigated are those of experimental vasography, roentgenologic study of the physiology of respiration and the circulation, the study of the diagnosis and the course of the diseases of the gastrointestinal tract, and, in particular, of ulcerative disease, as well as the study of the biologic effects of the roentgen rays. The roentgenologic approach to physiologic problems opens up possibilities heretofore but superficially investigated. The shift from investigations of a purely morphologic character to those of the functional activities of the human organism was made possible thanks to the recent advances in the roentgenologic methods and technic. The papers present much that should be of interest to the scientific roentgenologist. They are well illustrated and supplemented with exhaustive bibliographic references. The appearance of the volume suggests that the Russians are making progress in the art of book publishing.

Fractures and Dislocations for Practitioners. By Edwin O. Geckeler, M.D., F.A.C.S., F.A.A.O.S. Cloth. Price, \$4. Pp. 252, with 213 illustrations. Baltimore: William Wood & Company, 1937.

The author's purpose in writing a book on fractures and dislocations for general practitioners was to present the subject in a condensed manner without omission of important details. He desired to have the first physician who attended accident cases acquainted with one good method of treatment for every type of fracture and dislocation. Early correct care prepares the way for good end results. The book fulfils these requirements. One could easily take issue with many statements and therapeutic procedures but the author selected the most prac-

tical methods in order to facilitate the emergency therapy for the general practitioner. There are two parts, one on fractures and the other on dislocations. Every bone and joint fracture and dislocation is presented with a discussion of etiology, examination, complications, prognosis, immediate treatment and follow-up treatment. The manuscript is written in an easily understood manner. The illustrations, photographs and roentgenograms are well selected, clear and adequate.

Index médico-pharmaceutique. Par N. T. Deleanu, professeur à la Faculté de pharmacie de Bucarest, René Fabre, professeur à la Faculté de pharmacie de Paris, et L. Coniver. Avec la collaboration du Prof. M. Tiffeneau, et al. Préface de M. Maxime Radals, membre de l'Académie de médecine. Cloth. Price, 150 francs. Pp. 756. Paris: Masson & Cie, 1937.

This is a collaboration of Rumanian and French pharmacists to present "clearly and precisely" for physicians' and pharmacists' use the important facts regarding drugs and preparations. The main portion of the book is devoted to an alphabetically arranged index giving these facts in tabular form. There are introductory chapters on toxicology, pharmacodynamics and galenic preparations. Chapters on endocrine therapy, vaccines and serums and vitamins and a brief chapter on physical therapy and on narcotics and the laws relating to their dispensing conclude this book.

Miscellany

REGULATIONS GOVERNING ADMISSION TO UNITED STATES NARCOTIC FARM

The Surgeon General of the U. S. Public Health Service has forwarded the following regulations for admission to a U. S. narcotic farm, effective April 1, 1938:

No person shall be eligible for treatment or confinement in a United States narcotic farm unless he is an addict as hereafter defined and then only: (1) if such person has been sentenced to confinement on conviction of an offense against the United States, including convictions by general courts-martial or by consular courts; (2) if such person is completing a sentence of confinement at a narcotic farm and applies in accordance with the requirements of these regulations for further custodial care and treatment beyond the expiration of sentence; (3) if such person is placed on probation by any court of the United States or other federal authority which has imposed as one of the conditions of such probation that he will submit himself for treatment until discharged as cured, or (4) if such person, being not an unconvicted alien, voluntarily signs an application requesting custodial care and treatment in accordance with the requirements of these regulations. On admission to a narcotic farm as provided by these regulations, such four classes of addicts will be designated and hereafter referred to in these regulations as "prisoners," "ex-prisoners," "probationers" and "voluntary patients," respectively; collectively, they will be designated and hereinafter referred to as "addicts," "inmates," "patients" or "beneficiaries."

The term "addict" wherever used in these regulations means any person who habitually uses a habit-forming narcotic drug so as to endanger the public morals, health, safety or welfare or who is or has been so far addicted to the use of habit-forming narcotic drugs as to have lost the power of self control with reference to his addiction.

The terms "habit-forming narcotic drug" or "narcotic" wherever used in these regulations mean opium and coca leaves and the alkaloids derived therefrom, the best known of these alkaloids being morphine, heroin and codeine, obtained from opium, and cocaine derived from the coca plant; all compounds, salts, preparations or other derivatives obtained either from the raw material or from the various alkaloids; Indian hemp and its various derivatives, compounds and preparations, and peyote in its various forms.

A prisoner shall be admitted to a narcotic farm for treatment and confinement therein, on presentation to the medical officer in charge of such farm of a copy of the sentence and/or commitment, or other certificate showing the conviction, sentence of confinement and commitment of the prisoner, accompanied by

an order by the authority vested with the power to designate the place of confinement of the prisoner or of the authorized representative of such authority, designating such narcotic farm as the place of confinement and certifying that such convicted person is an addict. Such documents shall be supplemented by the certificate, or a copy thereof, to be executed by the prosecuting officer after conviction and sentence on a farm prescribed by the Surgeon General, stating his belief that the convicted person is an addict, his reasons for such belief, and all pertinent facts bearing on such addiction, together with the nature of the offense.

A prisoner, at the expiration of his sentence at a narcotic farm, may be considered for continued treatment therein as an "ex-prisoner" on submitting application to the Surgeon General on a form prescribed therefor. Such application must contain an agreement to submit to custodial care and treatment for the maximum time estimated by the Surgeon General as necessary to effect a cure or until he ceases to be an addict and be accompanied by a certificate from the medical officer in charge stating that at least one month prior to the expiration of sentence the prisoner has been examined, that he is still an addict, that he may by further treatment in a narcotic farm be cured of his addiction, and estimating the maximum time necessary to accomplish such cure. No prisoner shall be continued for treatment beyond the expiration of his sentence except on receipt of the Surgeon General's written approval of the application, and then only for such period of time as has been estimated as necessary to accomplish a cure.

A probationer shall be admitted to a narcotic farm for treatment on presentation to the medical officer in charge of an authenticated copy of the order entered by any court of the United States or other federal authority having power to suspend the imposition or execution of sentence and place a defendant on probation under any existing law, showing that such convicted person has been placed on probation and that the court or other federal authority has imposed as one of the conditions of such probation that such person shall be admitted and submit himself for treatment at a narcotic farm until discharged therefrom as cured of his addiction; such document shall be supplemented by a certificate executed after conviction by the prosecuting officer or probation officer on a form prescribed by the Surgeon General, such certificate stating the respective officer's belief that the convicted person is an addict, his reasons for such belief and all pertinent facts bearing on such addiction, together with the nature of the offense.

Any addict, except one who is an unconvicted alien, may be considered for admission to a narcotic farm for treatment and confinement therein as a voluntary patient on filing application with the Surgeon General on a prescribed form. Such applicant must agree to submit to custodial care and treatment for the maximum time estimated by the Surgeon General as necessary to effect a cure or until he ceases to be an addict. Unless he is a beneficiary of the United States Public Health Service as provided by law and regulation, such applicant must agree, if so required by the Secretary of the Treasury, to reimburse the government for his subsistence, care and treatment and accompany his application by a recognizance, stipulation, bond or undertaking in form and amount to be approved by the Secretary of the Treasury guaranteeing the cost of his subsistence, care and treatment. Such application must be accompanied also by a medical certificate executed on a prescribed form by a qualified physician designated by the Surgeon General. Such certificate must state whether the applicant is an addict, whether the designated physician believes that the applicant may by treatment in a narcotic farm be cured of his addiction, the estimated time necessary to effect a cure, and any further information bearing on the addiction, habits or character of the applicant that may be pertinent. No such addict may be admitted unless the application is approved by the Surgeon General and unless suitable accommodations are available after all eligible addicts convicted of offenses against the United States have been admitted.

The medical officer in charge shall not admit or accept responsibility for any addict applying or presented for admission to a narcotic farm when in doubt as to the eligibility of such addict or as to the sufficiency of the documentary evi-

dence presented to establish eligibility. In such cases he shall report the salient facts together with any recommendations he may desire to make to the Surgeon General for decision. Persons otherwise eligible may be refused admission when accommodations are not available or when appropriations are insufficient for their transportation, maintenance and care.

The actual and necessary expenses incident to the transfer to a narcotic farm of prisoners or probationers, including the actual and necessary round trip expenses of custodial officers required in the transfer of prisoners, shall be chargeable to the appropriation for the maintenance of such farm when authorized by the Surgeon General. No payment shall be made from such appropriation for any of the expenses of transporting to a narcotic farm ex-prisoners or voluntary patients.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Nonunion of Fragments of Fractured Tibia in Rachitic Child.—The plaintiff, when 21 months old, fell out of her high chair one night, fracturing her left tibia. The defendant saw her that night but made no effort to reduce the fracture until the following morning, when the child was taken to a hospital, the fracture reduced and a cast applied. About five weeks later the cast was removed but the child refused to walk and a new cast was applied. For months this process of applying and removing casts continued, the child refusing to walk each time a cast was removed. Finally an operation was performed, the ends of the fragments were scraped and a beef bone peg inserted. This treatment did not produce a union and the beef bone peg slipped down into the medullary canal of the lower portion of the bone. The defendant again operated, removed the peg, rescraped the ends of the fragments and sutured them together. This did not produce a union. The child was then taken by her parents to a clinic, where a homogenous graft was attempted but without success. A suit for malpractice was then instituted in the child's behalf by her father against the defendant. Judgment was rendered for the plaintiff, and the defendant appealed to the Supreme Court of Oklahoma, contending mainly that there was a total absence of competent medical testimony to show that the failure of the child's leg to heal was due to a lack of care or skill in his diagnosis and treatment.

There was evidence that the child had rickets, to which fact the defendant attributed the failure of his efforts to obtain a union of the fragments. The defendant was supported in the correctness of his diagnosis, in the propriety of the treatment he rendered and in his contention that the permanent nonunion resulted from the congenital condition of the bones and the presence of rickets by the positive testimony of ten other physicians. The only medical testimony apparently presented in behalf of the child was the deposition of two physicians, based on an examination not of the child but of roentgenograms taken of the fracture. The defendant contended that the testimony of these physicians did not conflict with the testimony of his expert witnesses. The court, however, pointed out that the plaintiff's witnesses criticized the defendant for not reducing the fracture immediately on the night of the injury, for not having roentgenograms taken with more frequency, whereby he might have studied the alignment, the apposition, the formation of callus, and other details of healing, and for failure to have an analysis of the blood made by which constitutional deficiencies might have been determined accurately and treated. They criticized, too, the cast applied and they condemned the insertion of the peg in view of its size, saying that it was bound to act as a foreign body and to irritate and to interfere with the functions of the medullary canal. They denied that the roentgenograms indicated any constitutional causes for the failure of the fragments to unite and contended that there was evidence of vitality in the bones at all times. One of them on cross examination stated that a roentgenogram indicated that nonunion was due to lack of apposition

and to irritation by a foreign body and to irritation caused by the ends of the fragments rubbing, as the result of the lack of fixation and apposition.

The Supreme Court was of the opinion that the plaintiff's testimony was of sufficient probative value to support a finding that the defendant did not diagnose and treat the child in keeping with the medical standards of the community and that the failure to obtain a union of the fractured bone was the result thereof rather than of any deficiency in the child's physical self. The judgment in favor of the child was accordingly affirmed. Two justices of the court filed a dissenting opinion.—*White v. Burton (Okla.)*, 71 P. (2d) 694.

Zoning Ordinances: Practice of Medicine Not a Trade or Industry.—A licensed physician was arrested pursuant to an affidavit which charged that on a stated day and at a certain address he violated the zoning ordinance of the city of Miami Beach, Fla., by "operating the profession of physician." He petitioned for and procured a writ of habeas corpus and was discharged from custody. The defendant in the habeas corpus proceeding, the chief of police of the city of Miami Beach, then appealed to the Supreme Court of Florida.

The zoning ordinance in question, said the Supreme Court, was entitled "An Ordinance to Regulate and restrict the Erection, Reconstruction, Alteration, Location and Use of Buildings, structures, land and water, for trade, industry, residence or other purposes." Section 2 of the ordinance, in dividing the city into certain area districts and restricting the use of land in some of these districts, provided:

In order to regulate and restrict the location of trades and industries and the location of buildings erected, constructed, reconstructed or structurally altered for specific uses, and to regulate the size of buildings and other structures hereafter erected or altered, to regulate and determine the size and dimensions of yards, courts and other open spaces and to regulate and limit the percentage of lot that may be occupied and the density of population, the City of Miami Beach Florida is hereby divided into use and area districts as follows.

The affidavit under which the physician was arrested charged that he violated the ordinance by "operating the profession of physician" at a stated address. But, said the court, engaging in the practice of medicine or, as was charged in the affidavit, "operating the profession of physician," is neither conducting a trade nor engaging in an industry. The ordinance, therefore, does not apply to the practice of medicine. If the affidavit should be held to charge an offense under the ordinance, then every physician who visited a patient outside the business district of and within the city of Miami Beach would necessarily be deemed to be doing so in violation of the ordinance.

The court accordingly affirmed the order of the lower court discharging the physician from custody.—*Yocum, Chief of Police, v. Feld (Fla.)*, 176 So. 753.

Privileged Communications: When Patient Waives Privilege by Testifying.—The plaintiff suffered certain injuries which he attributed to the negligence of the defendant. During the course of a suit for damages that ensued, the defendant sought to introduce the testimony of a physician who had treated the plaintiff prior to the accident. The trial court excluded this testimony, the intermediate appellate court reversed that ruling, and the plaintiff appealed to the Supreme Court of Ohio.

In Ohio a physician generally may not testify "concerning a communication made to him by his patient in that relation, or his advice to his patient." Such testimony is admissible by express consent of the patient or if the patient "voluntarily testifies, the . . . physician may be compelled to testify on the same subject." In the present case there was no claim that express consent was given by the plaintiff for the physician to testify. The plaintiff did testify in his own behalf. On direct examination he made no reference to the physician but did state that he had been in good health prior to the accident. On cross examination he admitted that he had consulted the physician but did not testify as to the ailment for which the physician treated him. But, said the court, this testimony on cross examination was not "voluntary" within the meaning of the statute. The plaintiff was obliged to answer the questions

whether he desired to or not. He had no choice about the matter and by so testifying he did not waive the privilege.

The defendant further contended that, when the plaintiff in his direct examination, which was voluntary, testified that his health before the time of the accident was good, he therefore testified on a "subject" under the statute in such a manner as to permit the defendant to introduce testimony respecting his health during that period, including the communications, advice and treatment of plaintiff by the physician who was offered as a witness. When the plaintiff so testified, the defendant contended, he thereby "opened the door" and waived the privilege accorded him by the statute. While, said the court, there is much force in such an argument, such an interpretation would render the statute useless and ineffective in every case in which the plaintiff or patient has testified generally respecting his health. One weakness of such an argument, the court pointed out, was illustrated by the manner in which counsel for the defendant in the beginning of his brief stated the question at issue. He said: "The only question in this case for the consideration of the court is: 'If the plaintiff in a personal injury suit voluntarily testifies generally as to his good physical condition at the time of the accident and prior thereto, can he, through his attorney, claim that the testimony of a physician who treated him for an ailment, *not loathsome*, for a period of six months or more before the accident, is privileged, . . .'" (italics supplied by the court). But, the court remarked, the statute makes no such distinction between an ailment which is loathsome and one not so. The statute is not concerned with any particular kind of ailment, whether loathsome or otherwise, but rather with the confidential relationship between physician and patient. What the patient has said to his physician and what the physician has said to the patient is closed to the outside world unless the patient first voluntarily testifies in respect thereto or gives express consent to its revelation.

The judgment of the intermediate appellate court was therefore reversed and that of the trial court affirmed.—*Harpman v. Devine (Ohio)*, 10 N. E. (2d) 776.

Hospitals for Profit: Liability of Owner of Hospital for Negligence of Hospital Nurses.—One of the defendants, a physician, owned and operated a hospital for profit. He assisted at an operation on the plaintiff, in the hospital, by another physician. Alleging that while in the operating room she had been burned by hot water bottles and that her burns had not been properly treated, she sued the physician owner of the hospital and one of the nurses who had helped to care for her, but not the physician who had performed the operation. A general demurrer interposed by the physician defendant was sustained by the trial court, and the plaintiff appealed to the Supreme Court of Idaho.

In her complaint, the plaintiff alleged, among other things, that the nurses applied the hot water bottles without instruction from or knowledge of the operating physician; that at the operation the nurses were not servants or under the control of the operating physician but were under the exclusive control and direction of the defendant physician; and that after her removal from the operation room, although the defendant physician and the nurses knew of the burns, they "did not administer to them in any manner." The demurrer to the complaint was sustained on the theory that the negligence, if any, was the nurses', who, though general servants of the defendant physician, as owner of the hospital, were during the time of the operation as a matter of law loaned to and became the servants of the operating physician. Hence, it was contended, no relationship of master and servant then existed between the defendant physician and the nurses so as to render him liable for their negligence. In the opinion of the Supreme Court, however, the trial court erred in sustaining the demurrer. In the first place, the complaint charged negligence on the part of the defendant physician and the nurses in failing to treat the burns after the patient was taken from the operating room. A hospital conducted for profit is liable for the negligence of its employees in the care rendered a patient subsequent to an operation. In the second place, the complaint alleged specifically that during the operation the nurses were not servants of or under the control of the operating physician but of the defend-

dant physician, and the court knew of no authority for holding that such a relation could not as a special circumstance legally exist.

The complaint, in the opinion of the court, stated a cause of action against the defendant physician, and the demurrer should have been overruled. The trial court, therefore, was directed to overrule the demurrer and to entertain further appropriate proceedings.—*Corcy v. Beck (Idaho)*, 72 P. (2d) 856.

Autopsy: Liability for Unauthorized Autopsy.—A widow, said the Supreme Court of Kansas, is entitled to receive, for the purpose of burial, the body of her husband in the same condition in which the breath of life left it. An autopsy performed on the body without her consent, unless by direction of or by the coroner when death has occurred under circumstances giving him jurisdiction, is a violation of that right for which she may maintain an action for damages against the physician performing it and a person assisting him in so doing. The fact that the unauthorized autopsy caused her mental pain and suffering only but did not cause her any physical injury will not defeat her right to recover damages.—*Alderman v. Ford (Kan.)*, 72 P. (2d) 981.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

55: 455-666 (March) 1938

- Basal Metabolism Standards for Children. F. B. Talbot, Boston.—p. 455.
- *Retardation of Growth in Diabetic Children. J. D. Boyd and A. H. Kantrow, Iowa City.—p. 460.
- Bacteriology of Blood in Rheumatic Fever. C. J. Leslie and Martha J. Spence, New York.—p. 472.
- Diet in Treatment of Diabetes Mellitus in Children. W. E. Nelson and Dorothy Ward, Cincinnati.—p. 487.
- Acute Encephalomyelitis Following German Measles. C. Davison and L. Friedfeld, New York.—p. 496.
- Acute Appendicitis in Children. W. J. Potts, Oak Park, Ill.—p. 511.
- Acute Cholecystitis Complicating Scarlet Fever: Report of Two Cases and Review of Literature. Ann T. Swing and J. G. M. Bullowa, New York.—p. 521.
- Use of Percombor Liver Oil as an Antirachitic Agent. R. L. Roddy, Elizabeth Kirk Rose, P. J. Hodes and J. C. Gittings, Philadelphia.—p. 526.
- Relation of Creatinine-Height Coefficient to Various Indexes of Nutrition. Amy L. Daniels, Mary K. Hutton and Bernice Neil, Iowa City.—p. 532.
- Vitamin B₁ Intake of Nursery School Children. Elda Robb, Ella M. Vahlteich and Mary S. Rose, New York.—p. 544.
- Hospital Infections: I. Survey of the Problem. C. F. McKhanna, Boston; A. Steeger, Santiago, Chile, and A. P. Long, Boston.—p. 579.

Retardation of Growth in Diabetic Children.—Boyd and Kantrow present data on 167 children with diabetes mellitus observed at the department of pediatrics prior to January 1935; physical retardation was noted in 6 per cent of the group (ten children), whose stature or rate of growth over long periods was markedly lower than the standard values used for comparison. The norms chosen as standards were those compiled by the Iowa Child Welfare Research Station. They find that, if diabetes mellitus in children is suitably controlled through adequate diet and through avoidance of frequent or continuous glycosuria, retardation of growth will be prevented or corrected. Physical retardation should be considered a result of nutritional or allied metabolic inadequacies rather than a consequence of endocrine disturbances unless prolonged observance of an ample dietary regimen has failed to maintain a normal rate of growth.

American Journal of Hygiene, Baltimore

27: 221-492 (March) 1938. Partial Index

- Survey of Intestinal Protozoa and Effect of Aldarson on Giardia and Other Intestinal Protozoa of Man. Veronica Armaghian and G. C. Medary.—p. 250.

Roentgen Visualization of Breast Lesions.—In diagnosing the types of mammary neoplasms roentgenologically, Hicken and his colleagues use one of two methods. The first is to inject the milk ducts with some radiopaque substance (stabilized thorium dioxide sol) and then make stereoscopic studies. The resulting "mammograms" present accurate anatomic patterns of the injected ducts. Any pathologic condition which alters their size, shape or conformation is readily detected. In the second procedure, termed "aeromammography," carbon dioxide is injected into the retromammary and premammary spaces in such a manner that the diffusing gas forms a contrast capsule around the parenchymal tissue and reveals any neoplasms that may be present. Contrast mammographic studies should be used when the simple roentgenograms are not informative, as they graphically portray the refined differentiation of anatomic relations and pathologic processes. Mammography encourages a patient to seek advice, for tumors can be correctly diagnosed without operation. Unnecessary mastectomies are avoided and mutilating radical procedures are not employed in hopeless cases. Complications are rare. During the last twenty-six months the authors have performed a total of 625 mammograms on virginal, lactating, involuting and diseased mammary glands. Within the early period of this study, three breast abscesses developed following the use of colloidal thorium dioxide. In two other instances the ducts were submitted to too much pressure and the smaller lacteals ruptured, permitting the compound to seep into the matrix structures, but only a mild nonsuppurative inflammation resulted. Refinement of technic and increased experience have eliminated these difficulties. Acute mastitis contraindicates all forms of visualizing studies as the manipulation activates the infective process. Such neoplasms as lipoma, fibroma, papilloma, cysts, galactoceles and carcinoma have been visualized and diagnosed by the two methods.

Pleuropulmonitis Following Irradiation.—Because of contradictory statements regarding the development of pleuropulmonitis following irradiation, Kaplan and Bell undertook a special study of the effects of intensive irradiation in seven selected cases treated over a period of from two months to two years. Roentgenograms in these cases were studied before, during and after treatment. Direct irradiation through the lung in the treatment of cancer of the breast is not advisable. That is why their method of roentgen therapy is limited to the tangential technic. All the patients were women with definite malignant lesions of the breast. High voltage roentgen therapy was employed exclusively, with additional irradiation in two cases by either the large radium pack or interstitial implantation

of radium needles. From their study they conclude that pleuropulmonitis, as described by others, occurs when cancer of the breast is treated by intensive irradiation with the rays passing through the lungs and may well be due to the technic employed or to a concomitant infection. Perhaps the explanation for postirradiation fibrosis in this anatomic site is identical with that in other sites. The pelvis, abdominal cavity or any parenchymal organ may be irradiated with no alteration in the absence of pathologic manifestations, but, when a concomitant infection is present, fibrosis ensues. Following the use of direct intensive irradiation of the breast, no pleuropulmonitis has occurred in any of the cases treated by the authors. In the treatment of the seven specifically selected cases they utilized varying factors of intensity and quality of radiation and direction of the radiation. With high voltage roentgen rays the depth dose is great, but the direction of the ray is tangential and perhaps that factor obviates pathologic changes in the tissue of the lungs. With the 5 Gm. radium bomb the depth dose is smaller, but because of the size of the field the beam is always directed into the lung. The intensities vary with x-rays and radium. Intensive irradiation when directed tangentially to the wall of the chest for carcinoma of the breast does not damage normal lung tissue.

Radiation Treatment of Herpes Simplex.—Hall treated fifteen patients for herpes simplex by irradiation. All the patients treated had herpes labialis. Several of them had more than one lesion at various times. In one patient the herpetic lesions appeared each month with menstruation, but in most of them no obvious cause for the eruptions could be found. The treatment factors used have been 130 kilovolts, 5 milliamperes, tube target distance 30 cm., without filtration. In more than half of the cases 375 roentgens with these factors has been administered in a single dose. This produced definite improvement. In several cases as little as 125 roentgens was used, but the results tended to show that most often this dose was too small. A liberal amount of normal skin was included on all sides of the area treated. The earlier the lesion is treated the better the result. Even in lesions forty-eight hours old the treatments tended to hasten the drying up of vesicles and to shorten the course of the affliction. In early cases it was not unusual for the tingling sensation to disappear within three hours and for the inflammatory reaction to be gone within from six to eight hours.

Gastrojejunalic Fistula.—Rife states that fourteen cases of gastrojejunalic fistula have been seen at the University Hospital in ten years. Thirteen cases were the result of posterior gastroenterostomy done for duodenal ulcer. One was

due to erosion by carcinoma of the stomach which involved a large segment of the transverse colon. The average age of the patients was 46 years. The interval between gastroenterostomy and definite symptoms of fistula varied from six months to eleven years, with an average interval of about four and one-half years. Operation was performed in ten of the thirteen cases resulting from ulcer, and two of the patients died. One patient died from peritonitis on the fourteenth day after excision of the fistula, closure of the colon and resection of the lower half of the stomach and a segment of the jejunum at the site of the fistula. The other death resulted from an abscess of the lung eighteen days after closure of the fistula and Finney pyloroplasty. Of the eight patients who survived operation, one died of acute lymphatic leukemia four and a half years after operation but had had no symptoms of recurrence prior to death. Two patients showed symptoms of reactivated duodenal ulcer, one four months and one six years after operation. In one case, in which a new anastomosis had been made, a new jejunal ulcer developed 3½ inches distal to the stoma; this was treated by resection of the jejunum, leaving the patient practically asymptomatic three years later. Of the three patients not operated on, one because of his age and absence of distressing symptoms was treated conservatively. He lived about four years after symptoms of fistula developed. Two patients refused operation. One died three weeks after leaving the hospital; the other has not been heard from since. The excision or the simple closure of the fistula, undoing of the old gastroenterostomy and reconstruction of the gastrointestinal tract to its normal state constitute the operation that has been used to the best advantage in the majority of the cases. In all cases in which operation is planned, a careful preoperative regimen designed to restore the body chemistry to as near normal as possible is imperative.

Gangrenous Cholecystitis and Partial Cholecystectomy.—Estes classifies seventy-eight consecutive cases of acute cholecystitis, all verified at operation, as five acute nonsuppurative, thirty-nine acute suppurative without demonstrable gangrene and thirty-four gangrenous. Of the gangrenous group, twenty-four showed stones impacted in the cystic duct and ten gave a positive culture from the gallbladder bile of either the colon bacillus (nine) or Staphylococcus albus (one). There were nine cases of perforation, seven with localized pericholecystic abscesses and two with acute general peritonitis. The only indication for immediate or emergency operation is the presence of symptoms of perforation with a spreading peritonitis. If gangrene is suspected, early operation must be definitely considered. Evidence of spreading or increasing suppuration or failure of some amelioration of the symptoms is an indication for prompt surgical intervention. The gallbladder should be removed whenever possible. Cholecystectomy from above downward will be found to be technically easier in these hugely distended, thick gallbladders. When the inflammation and induration extend to the area of the common duct, a partial cholecystectomy has proved exceedingly valuable. In the bad risk patient, cholecystostomy may be the only operation with a proper factor of safety. In the presence of jaundice and obvious involvement of the common duct, cholecystostomy should be considered the first part of a two-stage procedure, the second being a cholecystectomy with exploration of the common duct.

Lateral Sinus Thrombosis.—Irish reports on a study of 1,000 cases of cerebral vascular lesions found in 12,500 consecutive necropsies done at Los Angeles General Hospital. Of this number 133 were found to harbor cerebral embolic lesions, 418 hemorrhagic processes and 449 thrombotic pathologic conditions, among which ninety-eight (9.8 per cent) were sinus and venous thromboses. These ninety-eight cases of cerebral venous system involvement have been reviewed with an exposition of the comparative incidence of the various types of lesions, of the contributory factors and etiologic sources in their production and of the sex, age and survival periods in the patients demonstrating these intracranial pathologic changes. Lateral sinus thrombus was found present in thirty-eight cases, the sinus on the left being involved in twenty-five, on the right side in ten and bilaterally in three. The longitudinal sinus was involved in sixteen cases and the cavernous and its accessory sinuses in thirty-four; venous thromboses were disclosed in ten. The history of the development of knowledge regarding these conditions is reviewed with particular attention to diagnostic procedures, the sources and pathways of infection and the opinions regarding the surgical treatment. Bacteriologically the streptococcus is the causative agent of sinus thrombosis in 60 per cent of the cases, according to Seydell. Streptococcus mucosus is especially virulent and characterized by late exacerbations with fatal outcome. In chronic cases anaerobes and facultative anaerobes may be the causative organisms. In the majority of sinus thromboses the infection is from one organism.

Blood Cell Response to Sulfanilamide Therapy.—To determine the leukocyte response in patients receiving sulfanilamide, Bigler made daily blood counts and Schilling differential counts about the same hour of the day before, during and after sulfanilamide therapy in thirty-three cases. A dose of 15 grains (1 Gm.) of the drug to 20 pounds (9 Kg.) of body weight was closely adhered to. Patients with various types of infections as well as those with no apparent infection were included in the study. Of the thirty-three patients, twenty-seven had a leukocytosis and six had a leukocyte count within normal limits when sulfanilamide therapy was started. Not including the six patients to whom the drug was not administered until the infection subsided, there were twenty-one cases with a leukocytosis. In thirteen of these cases the leukocytes decreased to normal in a crisis-like manner within twenty-

four to thirty-six hours after the subsidence of the fever. In seven cases the white cells returned to a normal level in a lysis-like manner only after forty-eight hours or more, while in one case the leukocytosis did not change. Of the six patients with a normal white cell count to whom the drug was administered, a moderate leukopenia without neutropenia developed in two. In the other four the leukocyte count did not change. The alteration in the leukocyte response was in the nature of a marked absolute reduction of all the cell elements without any characteristic relative change in the proportion of the different white blood cells as studied by the Schilling count. In the majority of cases the Schilling differential count reflected only what one could consider a healing infection. An increase in the leukocyte count attributable to the sulfanilamide did not occur in a single case. In six of seven patients without an infection but with a leukocytosis there was a rapid decrease of the white cells to a normal level when the drug was administered. From this it would seem that the beneficial action of sulfanilamide is due to its own action in the blood stream rather than to its enhancing the power of the leukocytes or increasing their number to control the infection.

Metrazol Shock Treatment of "Functional" Psychoses.

—Low and his associates discuss the sixty-six patients with functional psychoses whose treatment with metrazol was terminated by the middle of September 1937. Patients with psychoses associated with "organic" disease were excluded. To thirty of the sixty-six patients metrazol was given first, administration of metrazol to nine patients was preceded by a course of insulin shocks, in eleven by narcosis, in nine by fever and in seven by fever and narcosis. Metrazol is administered by the intravenous route in a 10 per cent solution. As a first dose 4 cc. of the 10 per cent solution to women and 5 cc. to men is given without regard to body weight. It is important to administer the drug with the greatest possible speed, and the use of a 20 gage needle is advisable. Most patients acquire a tolerance which necessitates a progressive increase in the dose. The treatment gave a relatively high rate of recovery for persons with manic-depressive conditions and those "without psychosis." For the schizophrenic group, treatment yielded a relatively high rate of recovery only if given within six months after onset of the disease. For manic-depressive conditions the superiority of the metrazol treatment to that with prolonged narcosis appears evident; it has increased the rate of remission and reduced the incidence of dangers and complications. The claim advanced by some authors that the outlook for recovery is proportional to the "convulsive threshold" of the patient is not substantiated by the present investigation. Contrary to the assertion of some investigators, the metrazol paroxysm differs in several respects from the "grand mal" attack of cryptogenic epilepsy.

Mechanism of Migraine Headache.—Graham and Wolff found that changes in the intensity of migraine headache are related to changes in amplitude of pulsations of branches of the external carotid arteries. Factors that decreased the

amplitude of the pulsations decreased the intensity of the headache and vice versa. Reduction in the amplitude of pulsations of the temporal artery by manual pressure on the common carotid artery of the affected side was accompanied by reduction in the intensity of the headache. Distention of the temporal artery by increasing experimentally the intramural hydrostatic pressure resulted in pain. Ergotamine tartrate, in diminishing the intensity of migraine headache, reduced the amplitude of pulsations of the aforementioned arteries by about 50 per cent. Observations and photographs made before and during the action of ergotamine during thirty-two attacks of migraine in sixteen subjects revealed vasoconstriction of the temporal and middle meningeal arteries. These data support the postulate that the head pain of migraine is produced by distention of the cranial arteries and that termination of the headache by ergotamine tartrate is due to its capacity to constrict these cranial arteries and thus reduce the amplitude of their pulsations.

Calcification About the Flexor Carpi Ulnaris Tendon.

—Milch and Green encountered patients who presented sharply localized pain and tenderness over the area around the pisiform bone, a pathognomonic limitation of motion at the wrist, occasional signs suggesting an inflammatory reaction, a characteristic roentgenogram showing calcification and early subsidence of symptoms. Though all the cases showed a similarity, there seemed to be sufficient variation to justify subdivision into three main types: (1) a hyperacute form, (2) an acute form with calcification and (3) an acute form without calcification. In the absence of any pathologic specimen they have inferred the location of the calcium deposit. No definite etiologic factor can be established. Case 1 suggests an infectious origin. On the other hand, in the case reported by Cohen and in cases 3 and 5 the symptoms are so definite that the relation of trauma or overuse cannot be denied. In the other cases such a definite traumatic etiology could not be established, though it seems to be of more than casual significance that the prominence of the pisiform bone, into which the flexor carpi ulnaris tendon is inserted, is the area that is normally brought into contact with the desk or table top. Because of the abrupt mode of onset of the symptoms and their rapid subsidence under treatment, a traumatic origin seems likely, but an underlying focus of infection, a rheumatic diathesis or a metabolic disturbance cannot be categorically excluded. Apart from the tenderness, swelling and limitation of motion, the characteristic feature is the appearance of the radiopaque substance situated near the pisiform bone. The calcific shadow may appear as a delicate lacework or in more solid masses. It may be circular, oval or elongated. In all probability the size and shape of the shadow depend on the stage of the process and the intensity of the reaction. The condition must be differentiated from a stenosing tendovaginitis or an acute infectious process and roentgenographically from osteomyelitis or periostitis of the pisiform bone, an accessory carpal ossicle

or an old comminuted fracture of the ulnar styloid. Surgical exploration has not been found justifiable. Usually simple rest on a splint, application of heat and administration of salicylates have resulted in prompt disappearance of the symptoms.

Agglutination of Salmonella and Dysentery Suspensions by Serums.—Desranleau and his associates examined groups of from 100 to 200 control serums from persons in Montreal and a group of fifty-eight serums from hospital patients, the majority of whom were ill with nonenteric febrile disease, in respect of their ability to agglutinate various salmonella, dysentery and brucella suspensions. The more important features of the results obtained include the following: the usual discrepancy between the *Salmonella typhi* H titers of male and those of female serums; a curious discrepancy between the *Salmonella aertrycke* specific titers of these two groups of serums; the comparatively wide distribution of *Bacillus dysenteriae* Flexner X and Y agglutinins; the similarity between the *Flexner dysenteriae* titers of the male and those of the female serums; the similar incidence of *Flexner dysenteriae* agglutinins in the control serums and in the serums of patients suffering from nonenteric febrile diseases, and the infrequent occurrence of high or moderately high titers of agglutinins for *Brucella abortus*, *Salmonella paratyphi* C sp. and *Bacillus dysenteriae* Sonne in the serums examined. Moderately high titers of agglutinins for *Bacillus dysenteriae* Flexner were encountered in the Montreal serums with a frequency much greater than that reported to have been found in serums from the general population of British Columbia.

 *Study of Blood Sedimentation Test in Pulmonary Tuberculosis: Preliminary Report. A. J. Logie, Jacksonville.—p. 491.

Blood Sedimentation in Pulmonary Tuberculosis.—Logie performed 148 sedimentation tests in fifty-three cases of tuberculosis. There were fifteen patients (group A) who over a period of six months showed few if any clinical signs of any active pulmonary lesion, with stationary or regressive x-ray signs, negative sputum or occasional positive results on concentrated examination of the sputum or gastric contents. In this group the male curve falls to 25 mm. within the first fifteen minutes and to 46 mm. in one hour, the female curve to 39 and 64 mm. respectively. Group B (twenty cases) represents the average curves of those cases in which there was slight to moderate activity. For the males the curve falls to 55 mm. in the first fifteen minutes and to 67 mm. in one hour, and for the females to 60 and 69 mm. respectively. Group C represents those cases in which there was moderate to marked activity. The male curve falls to 67 mm. in fifteen minutes and to 76 mm. in one hour, while the respective female curve declines to 68 and 76 mm. These results enable one to classify the tuberculous cases according to activity. Using the Brooks

method, the author considers the first fifteen minutes of the test (induction period) more significant than the type of curve over one hour of observation. As a variable degree of anemia is present in the majority of tuberculous cases and as the sedimentation rate is usually accelerated in anemia, he feels that a single sedimentation rate may establish a faulty criterion unless corrections are made by hematocrit estimations or the average of several rates taken at different intervals. The study corresponds with the reports of other investigators that in pulmonary tuberculosis the sedimentation speed of the blood increases with the activity of the disease. Artificial pneumothorax decreases the sedimentation rate slightly, if not immediately after a refill. The diminished congestion brought about by the procedure is believed to be the underlying cause. After a comparative study of the leukocytic index it was evident that the sedimentation rate gave more reliable information as to the progress of the disease in the patient.

Quinine in Myotonic Dystrophy and Congenital Myotonia.—Kolb and his collaborators describe the effect of quinine, dimethyl carbamic ester of hydroxy phenyl-trimethyl ammonium methyl sulfate, the physostigmine derivative and other drugs in eight cases of atrophic and in one of congenital myotonia. The action of quinine in two cases of myasthenia gravis is discussed. Three daily dynamograph records were made of four patients: during a control period, during a period in which quinine alone was given, when quinine and the physostigmine derivative were administered, and during a control period. These were recorded graphically and the tracings obtained provided an objective estimate of the therapeutic effect and antagonistic action of each drug. Quinine sulfate abolished the myotonus but had no effect on muscular strength. Quinine sulfate counteracted the effect of the physostigmine derivative in two cases of myasthenia gravis and increased the symptoms and signs of the disease. The physostigmine derivative increased myotonus and directly antagonized the full therapeutic effect of quinine sulfate. Parathyroid extract, potassium chloride and adrenal cortex extract failed to reduce myotonus.

Incidence of Tuberculosis in Diabetes.—Ralli and Steinberg investigated the occurrence of tuberculosis in the 748 diabetic patients attending the Diabetic Clinic of the Third Medical Division (Bellevue Hospital) and the Diabetic Clinic of New York University College of Medicine. The observations were made over a period of seven years. Of the 748 patients, thirty-three had active pulmonary tuberculosis, an incidence of 4.3 per cent. Excluding the one patient who was 79 years of age, the average age was 47.8 years. In twenty-nine cases the onset of the diabetes preceded any signs or symptoms of tuberculosis. The diets used by these patients were high in carbohydrate, moderate to high in fat and with a protein intake of from 65 to 85 Gm. All but one patient required insulin, and twenty-two of them required more than 30 units daily. Ten of the patients received pneumothorax. Two had, in addition, pneumolyses which were not successful. In one case there was hemoptysis which could not be controlled by pneumothorax or phrenicotomy, and the patient finally died of a bronchiogenic spread. Five of the patients, during their hospital period, left against advice and any further information about them could not be obtained. Thirteen of the thirty-three patients observed have died since they acquired tuberculosis. Ten no longer attend the clinic but as far as is known are still alive. Five of the remaining ten are now attending the diabetic clinic, having been treated successfully for their tuberculosis. The remaining five are at present in sanatoriums. In three of the five patients attending the clinic the disease is considered inactive. As the tuberculous diabetic patient is apt to have diabetes in a severe form the authors have found it advisable to give feedings four times in twenty-four hours, as the usual three meals leave the patient with no outside source of energy for a period of fourteen hours, during which time he would be forced to burn his body stores. Insulin is given with each feeding in amounts sufficient to keep the patient approximately sugar free and always acetone free. The intake of fluid and salt should be adequate. Diabetic patients become dehydrated

very readily, particularly in the presence of an infection. Therefore the patients are advised to drink ample amounts of water and to take a slight excess of salt. Normally a person takes in approximately 4 Gm. of sodium chloride as such daily. For severely affected tuberculous diabetic patients this should be increased to 6 Gm. daily or more if necessary. An adequate intake of calcium is assured by having the patient take at least three glasses of milk daily.

Bacteriostatic Action of Sulfanilamide Compounds on Sporulating Anaerobes.—Spray measured the bacteriostatic action of sulfanilamide, disulfanilamide and prontosil soluble on sporulating anaerobes commonly causally associated, alone or in combination, with human gaseous gangrene. The drugs exert an apparently specific selective action against certain species, notably *Clostridium tetani*, *lentoputrescens*, *novyi*, *septicum* and *histolyticum*. On the contrary, *Clostridium welchii* and the intensely proteolytic types, such as *Clostridium sporogenes* and *bifermentans*, as well as the toxic *Clostridium botulinum* type A, are scarcely affected, at least by any concentrations tolerated by human beings. The bacteriostatic activity increases in order: prontosil soluble, sulfanilamide and disulfanilamide. These results parallel those of Rosenthal, Bauer and Branham in testing these compounds for protection of mice against streptococcal and meningococcal infection. Admitting Bohlman's "dramatic" results in the treatment of three cases of presumably *Clostridium welchii* infections with sulfanilamide, it would seem necessary to assume some secondary therapeutic activity of the drug other than a simple and direct bacteriostatic action on the bacteria themselves.

Effects of Ethyl Alcohol on Metabolism.—Grubbs and Hitchcock determined the effects of small amounts of ethyl alcohol on the respiratory exchanges during rest and work. Two series of experiments have been carried out on five different subjects, on whom a total of more than fifty tests were made. In the first series of experiments three subjects were used. With these subjects both control and alcohol tests were run while the subject was lying in a basal condition, while he was sitting at rest on a bicycle and while he was pedaling the bicycle at a rate of from 2,500 to 3,000 foot pounds of work per minute. In basal tests the subject reported to the laboratory in a postabsorptive condition. One or two basal metabolism determinations were made. The subject then ingested 200 cc. of water if the test was a control test, or 200 cc. of

about 10 per cent alcohol in alcohol tests. The quantity of alcohol given was from 0.25 to 0.3 Gm. per kilogram of body weight. In the work tests the dosage of alcohol was the same as that used in basal tests. In the second series of experiments about the same quantity of alcohol was ingested, but in this case it was diluted with 200 cc. of a 10 per cent solution of dextrose. Alcohol produced no specific dynamic action during the first two hours following its ingestion. There was no significant change in the ventilation equivalent or in the alveolar carbon dioxide following the ingestion of alcohol. Utilization of alcohol while resting was greater when given with dextrose than when given alone. The rate of oxidation of alcohol in the body was higher in the sitting position than when reclining and still higher when working on the bicycle ergometer than when sitting at rest. The results are interpreted as presumptive evidence that the muscles are capable of using the energy of ethyl alcohol in the performance of work.

Conservative Management of Appendical Peritonitis.

Adams and Bancroft used the conservative method in treating 110 cases of appendical peritonitis in children less than 16 years of age. The surgical and pathologic observations have been analyzed in ninety-four cases in which deferred appendectomies were performed. The conservative treatment consisted of rest, continuous gastroduodenal siphonage, hot applications to the abdomen, para-oral fluids and sedatives. An incidence of more than 10 per cent in major exacerbations was observed. Deferred appendectomy is imperative in every case. The mortality in the 110 cases was 4.5 per cent. There were no deaths in the group of ninety-four deferred appendectomies. The duration was forty-eight hours or less in fifty-three cases; the largest group of cases was observed in the period between thirty-six and forty-eight hours, three, four and five days in thirty-three and widely scattered in twenty-four. There were no deaths in the extended group; all fatalities occurred in cases with histories of duration from thirty-nine to ninety-six hours. The authors consider the duration as only one factor determining the course of treatment. The progress of the disease is probably of the greatest consequence; it might be better to speak of uncomplicated and complicated rather than of early and late appendicitis. The temperature and pulse on admission were found to be of considerable assistance in deciding the question of operative or conservative treatment. The average temperature and pulse in all cases of complicated appendicitis treated conservatively was 101.7 F. and the pulse 119 per minute. In the typical case the temperature was from 102 to 103 F. with a rapid pulse of from 130 to 150 per minute. The figures are well above those ordinarily seen in cases of uncomplicated appendicitis. Many cases coming in late (after five days) tend to lower the general averages. The infection has often become well localized with a large mass in the right lower quadrant, the result sought in the conservative treatment having already been accomplished. The leukocyte count varied from 30,000 maximum to 7,400 minimum. In the late cases and those with generalized peritonitis the figure is often low, indicating a poor response to infection. The typical white blood count was more than 20,000, with 85 or more neutrophils per hundred cells. The general condition of the patient should always be evaluated as completely as possible. The state of hydration and degree of

toxicity may be of considerable assistance in deciding on operative or conservative therapy. Separation of the loops of intestine by fluid could frequently be demonstrated roentgenologically in cases of generalized peritonitis. The average duration of fever in all cases treated conservatively was 9.2 days.

Closed Internal Pneumonolysis in Pulmonary Tuberculosis.—Drash discusses the outcome of 251 separate pneumonolyses performed on 230 patients. The operation has been performed by the high frequency current and the Davidson thoracoscope. Most of the patients were receiving pneumothorax refills for from four to six months or longer. The only valid contraindication to pneumonolysis is the existence of an acute pleurisy with fluid, either serous or purulent. Successful operations can be done in chronic afebrile cases of pleurisy with effusion, provided the adhesions are not covered with fibrin and can be clearly seen. The general results, exclusive of complications, have been most satisfactory. There have been no deaths attributable to the operation. Of the cavities present, 74.8 per cent were closed. A satisfactory collapse was obtained in 86.4 per cent of the patients operated on. Sixty-four patients (27 per cent) had fluid in the pleura at the time of operation. Fourteen additional patients (6 per cent) had fluid after operation, mostly within a few days. Among the total of seventy-eight patients (33.6 per cent) who had fluid at one time or another, in six the fluid became purulent. The total incidence of clear fluid and of tuberculous empyema in the present series is well within the limits of corresponding incidence to be expected from pneumothorax alone. Therefore the evidence indicates that pneumonolysis is not an important factor in the development of intrapleural fluid. Only one patient had tuberculous empyema within less than five months after operation. Five (of ninety-nine operated on) of the six patients with tuberculous empyema came from one institution which has a high proportion of patients with moderate and far advanced pulmonary tuberculosis. Rupture of a cavity into the pleura occurred in three of these, followed

immediately by death. As they occurred three and one-half, four and one-half and nine months after operation, they were not ascribed to it.

Tuberculous Empyema.—Woodruff reviews 154 cases of tuberculous empyema occurring in the practice of local physicians and sanatoriums, with a follow-up of from three to eight years. There were forty-seven known persistent bronchopleural fistulas and forty-two known secondary infections. About half were infected from the onset by either rupture of the lung or contamination of the pleura. The rest began as straight tuberculous fluids and became infected later. Of those patients who originally had a noncontaminated tuberculous empyema and lived long enough to acquire other complications, 30 per cent finally had them either by perforation or by secondary infection. The death rate is about 30 per cent in the uncontaminated tuberculous group and about twice that for the mixed infections and for the fistulas. The problem of all empyemas is a dual one: the infection itself and the abnormal pleural space. The attempt to control the former without obliteration of the latter is difficult although sometimes possible. About 70 per cent of the straight tuberculous group have survived the infection to date.

Late Results of Insulin in Malnutrition.—Blotner had fifty-four women and forty-six men who were ambulatory and normal physically except for from moderate to severe malnutrition, and who had tried to gain weight by one method or another but without success. The patients usually injected 10 units of insulin three times a day about twenty minutes before meals. A few took insulin twice a day, and in rare instances the dose was increased to 20 units two or three times a day. The insulin was usually taken for from one to three months, the shortest period being two weeks and the longest seven months. A liberal diet was advised. The immediate effects were a gain in weight and an improvement in appetite, which varied in individual patients. In most cases the gain was from 3 to 4 pounds (1.3 to 1.8 Kg.) a week for the first two or three weeks; it became less marked as time progressed. Finally, the weight remained constant regardless of the administration of insulin. Most of the patients observed an improvement in general and mental condition, an increase in strength and efficiency and a better gastrointestinal function. The gain in weight appeared to be due to an actual increase in the deposit of fat and not to edema, suggested by the measuring of the fluid intake and output. The weight was followed for from one to

six years after the cessation of insulin treatment. Of the twenty-six patients observed for one year after discontinuing insulin, seventeen retained the added weight, six lost it all and three patients followed for two years, five maintained the gain, three lost the added weight shortly after discontinuing insulin and four held the weight for approximately a year and then lost it gradually during the subsequent year. Of the nineteen patients followed for three years, eleven maintained the gained weight, four lost it all within six months and four kept the weight for approximately one year and then lost it slowly over varying periods. Of the forty-three patients followed for from four to six years, twenty-six held the added weight, ten maintained the gain from one to two years and then lost it during varying intervals and seven retained about half the gained weight. Ten of the patients, listed as maintaining their added weight, continued to gain after discontinuing insulin. Four patients became from 10 to 35 pounds (4.5 to 16 Kg.) overweight for their age, height and sex; one of them became definitely obese. In some patients there was a decrease in the sugar tolerance during the period of insulin treatment, but this returned to normal shortly after discontinuing insulin. There was no permanent impairment of the carbohydrate tolerance.

Public Health: A Concern of the Government. S. J. Kopetzky, New York.—p. 444.

Habitual Abortion.—Rosenfeld has been treating twenty cases of habitual abortion with about 5 cc. of normal pregnancy serum injected intramuscularly once a week. Should staining or bleeding occur during the course of pregnancy, the patient is put to bed and doses up to 10 cc. may be given two or three times a week or even daily depending on the signs and symptoms. In the absence of bleeding, patients are permitted to pursue their normal routine and duties. The diet is that usually prescribed for a normal pregnant woman with the addition of cod liver oil and viosterol. Of the twenty patients, nineteen gave birth to normal living infants.

Unusual Types of Typhoid Infection.—Lantin and Morales cite three cases of typhoid in which no evidences of active or healed typhoid lesions were found in the intestine at necropsy. The clinical diagnosis of typhoid in case 1 was based principally on the persistent fever and the positive blood culture irrespective of the high leukocytosis. The diagnosis of typhoid was also made in case 2 because of the persistent high fever and two successive reports of positive blood culture. Case 3 is considered interesting only because of its comparative rarity for, as far as can be determined, it is the first case ever reported in the Philippines of typhoid meningitis occurring in the course of ordinary typhoid and confirmed by postmortem examination. Diagnosis of typhoid meningitis in this patient was based principally on clinical symptoms and signs of the disease, on the isolation of *Bacillus typhosus* from the purulent spinal fluid and on the purulent exudate from the meninges, made at necropsy, and further corroborated by the characteristic cellular observations in histologic sections of the brain and meninges.

Irradiation Sickness.—Martin and Moursund believe that true irradiation sickness is in most instances produced by an interference with intestinal function, so they have searched for remedies capable of counteracting functional disturbances of the intestinal tract. Best results have been obtained from the intravenous administration of a liter of 5 or 10 per cent dextrose made up in physiologic solution of sodium chloride. This medication can be given repeatedly and is particularly helpful in the treatment of cases in which abdominal masses are producing partial intestinal obstruction. Holmes and Hunter believe that a high carbohydrate intake is helpful. Davis states that a lack of vitamin B₁ produces anorexia and degenerative changes in the intestinal tract. A series of animal experiments was carried out in an effort to show that thiamin chloride (crystalline vitamin B₁ hydrochloride) might be capable of producing protection against the lethal abdominal dose of x-rays. Although small animals could not be uniformly protected, large doses of thiamin chloride seemed to prolong definitely the lives of some of them. The substance was tried in clinical practice. The drug is given by mouth, and intramuscular injection is resorted to only when vomiting occurs. This form of medication not only reduced or completely abolished all nausea but enabled the patients to enjoy most of their meals and to maintain their nutrition even while receiving a long series of treatments over the abdomen. In many instances nausea and vomiting occurred during the first few days of treatment but completely disappeared during the remainder of the period, which often lasted for several weeks. It appears that several days is required for the body to become saturated with the substance. For this reason 2,000 international units is given daily for at least two days before treatment is started. This procedure has definitely minimized the symptoms observed during the early period. That saturation is necessary for relief is also indicated by the fact that, when vomiting occurs, it can frequently be relieved almost immediately by the intramuscular injection of 2,000 international units of thiamin chloride. The following routine for patients about to undergo heavy irradiation has been adopted: 1. A high carbohydrate diet is given. 2. Thiamin chloride 2,000 international units is given daily by mouth, beginning two days before the irradiation is started. 3. If vomiting occurs, 2,000 international units of thiamin chloride is given intramuscularly. 4. If relief does not occur within thirty minutes, 6 grains

(0.4 Gm.) of sodium amytal or an equal amount of another soluble barbituric acid derivative is given by rectum or a pentobarbital sodium suppository is inserted. 5. If vomiting persists, 1 liter of 5 per cent dextrose in physiologic solution of sodium chloride is given intravenously and repeated if necessary. As a rule, dextrose intravenously is needed only when some serious complication such as partial intestinal obstruction or abdominal infection is present.

Response of Bone Marrow and Lymph Nodes to Hyperpyrexia.—Doan made a study of the cellular reactions during hyperpyrexia induced by the hypertherm and fever induced by the intravenous inoculation of typhoid vaccine and by malaria inoculations. There is a rather constant hemopoietic response to "fever" and the majority of the cells making up the postfebrile leukocytosis are polymorphonuclear neutrophils newly delivered by the bone marrow. This part of the reaction may be nonspecific. There is a destruction of lymphocytes during hyperpyrexia. There is probably some destruction or redistribution of monocytes, as shown by a delayed monocytosis made up primarily of younger forms. The hemograms following malaria and *Bacillus typhosus* inoculations differ from those observed during fever induced by physical methods in the marked leukopenia during the chill, in the temporary disappearance of the monocyte from the circulation following typhoid and in the marked stimulation of the monocyte in malaria and its moderate stimulation following typhoid vaccine. The shift to the left in the neutrophilic granulocytes in malaria is noteworthy and the appearance of clasmotocytes in the peripheral blood has been observed with no other type of fever study. The profound stimulation of phagocytic clasmotocytes observed in malaria provides an important cellular defense weapon in the treatment of syphilis of the central nervous system, which is not available when other fevering methods are employed. While biopsy of the sternal marrow following hypertherm fever therapy did not show an increase in clasmotocytes, there was a tremendous increase in these phagocytic cells elsewhere in the tissues, more especially in lymph nodes, spleen and liver. To that extent, at least, artificial hyperthermia by physical means not only provides the thermal factor of importance for the inactivation of *Spirochaeta pallida* and the gonococcus but has now been demonstrated to exert a profound effect on the cellular equilibriums of the body.

Visceral Metastasis from Rectal Carcinoma.—From a study of 170 rectal carcinomas with complete postmortem observations, Brown and Warren attempt to evaluate the importance of invasion of the local blood vessels as compared with neoplastic lymph nodes in predicting the occurrence of visceral metastases. They observed also the influence of such factors as the histologic type, extent and location of the primary growth, duration of the disease, age and sex on the development of visceral metastases. This series represents only a

portion of patients with rectal carcinoma treated in four hospitals over a period of ten years. The tendency of rectal carcinoma to metastasize by way of the blood stream varies in general with the degree of differentiation. Malignant adenoma produced visceral metastases in 23 per cent of the cases, adenocarcinoma in 49 per cent and carcinoma simplex in 56 per cent. Mucinous carcinoma has a marked tendency to metastasize by way of the lymphatics. The longer the duration of rectal carcinoma, the greater are the number of visceral metastases. There was a 5 per cent metastasis of rectal carcinoma to bone. The more the primary growth penetrates the intestinal wall, the greater are the chances of blood-borne metastasis. The reliability of prognosis of visceral metastases by observation of local intravascular invasion, and to a less extent by lymph node metastasis, increases with the duration of the disease. Visceral metastasis was observed in 41 per cent of the cases; 61 per cent showed local intravascular invasion and 67 per cent of these showed visceral metastases, closely paralleling the 66 per cent of visceral metastases with positive lymph nodes. Only one case of the seventy showing visceral metastases failed to show local intravascular invasion, whereas twenty-four of these cases failed to show positive lymph nodes; that is, 24 per cent of the patients with negative nodes had visceral metastases. Sections of the primary growth in rectal carcinoma should be scrutinized carefully for invasion of capillaries or veins by tumor, because intravascular invasion frequently means visceral metastases, and its absence, provided at least three sections from different parts of the growth are examined, nearly always rules out visceral metastasis. Its efficiency in predicting visceral or bone metastasis outranks that of neoplastic lymph nodes.

Vitamin Oils in Treatment of Burns.—Puestow and his associates produced controlled burns on pigs and rabbits and treated them with ointments containing varying amounts of vitamin A and vitamin D. The time and character of local wound healing was determined and compared with untreated controls and burns treated with tannic acid. Burns treated with 5 per cent fresh tannic acid solution healed in the same length of time as untreated controls of similar average size. The application of vitamin free olive oil ointment to slightly larger burns was followed by complete healing in the same length of time as the controls. Cod liver oil ointment shortened the period of healing by 25 per cent. Burns which averaged 50 per cent larger than the controls were treated with three high vitamin ointments: containing no vitamin A but high in vitamin D, having a low vitamin A to vitamin D ratio and having a high vitamin A to vitamin D ratio. The time of healing was approximately 25 per cent shorter than in the smaller control lesions and those treated with tannic acid. It was no longer than in the smaller lesions treated with cod liver oil ointment of low vitamin content. The response to the various high vitamin ointments employed was approximately the same. Histologic studies of the scars of all healed burns revealed no characteristic difference for the various therapeutic agents employed.

Old Tuberculin.—Cary has frequently observed certain intra-ocular and extra-ocular lesions which responded to the intradermal use of old tuberculin. Occasionally a lesion of the middle ear, unresponsive to any local treatment, was cured promptly following intradermal injections of old tuberculin.

There are many inflammatory reactions difficult to classify which readily subside when old tuberculin is used. Lesions which respond favorably to old tuberculin do not occur in active tuberculosis. Persons who are allergic and who have developed this hypersensitivity from an early infection, which has been well circumscribed, need not be disturbed greatly by the cautious use of old tuberculin. The author uses one-fourth minim (0.016 cc.) of stock old tuberculin intradermally in the beginning and increases the quantity as needed.

Underweight Patients Treated with Insulin.—The McCastors treated fifteen underweight adult patients with insulin plus high caloric diets combined with vitamins. The typical patient in this group presented the picture of malnutrition—the long asthenic type with visceroptosis and anemia. Gastrointestinal symptoms were most prevalent; nausea, constipation, flatulence, dizzy spells, lethargy, vague back and leg pains were listed by some of the group. Anorexia also was a common symptom, while others simply could not gain weight in spite of good appetites. All had tried various plans for gaining weight. The initial dose of insulin was from 5 to 30 units two or three times daily. Some who were employed found it impossible to take the midday injection. Each patient was given a diet sheet with instructions to keep a food diary. Additional vitamins also were given. The activities of the patients were in no way curtailed. The increase in weight varied from 4 pounds (1.8 Kg.) in two days to 18 pounds (8 Kg.) in twenty-two days. Striking changes were displayed in the patients in from three to five days after the initiation of treatment. The hypochondriac was no longer conscious of his "heart pain," backache and fits of depression. Reactions were both local and general. Four patients at about 11 a. m. experienced subjective symptoms of nervousness and dizziness with a slight degree of nausea. This was soon eliminated by the taking of sugar at 10 a. m. All but two of the patients were candidates for various civil service appointments for which weights were specified.

Regional Irradiation in Treatment of Lymphadenoma.—Levitt considers the third stage of lymphadenoma (multiple lesions with visceral involvement and advancing cachexia) and its treatment by wide regional irradiation (roentgen bath) which has been in use at St. Bartholomew's Hospital for ten years. If precautions are observed, doses of x-rays can be applied with safety to extensive regions of the body, e. g., the whole abdomen or the whole chest, which are comparable with the doses ordinarily given to localized lesions. The method is applicable to the treatment of lymphadenoma and of radio-sensitive malignant neoplasms such as seminoma. The thoracic bath is indicated in cases in which the disease involves the mediastinum and lung fields, with or without axillary and cervical glands, or the mediastinal and axillary, with or without cervical glands. Masses in the abdomen without known thoracic involvement require an abdominal roentgen bath. The trunk bath is not without danger, and at present it is being used only in selected cases of both thoracic and abdominal disease in which the general condition of the patient has not deteriorated too far. High voltage rays are used with four oblique fields, overlapping completely. The focus skin distance must be sufficient to cover fully the area exposed. The patient is carefully protected by lead rubber from radiation above the upper limit and below the lower limit of the fields to be exposed. The whole section of the patient is exposed to the beam in each case. Treatment is begun with small doses, which are gradually increased until the patient is taking daily doses to large sections of the body. In the thoracic bath the two anterior oblique fields are applied with the patient in the supine position and the two posterior fields in the prone position. Treatment is begun with thirty-five surface roentgens to one field. The fields are treated in turn day by day, and the dosage is increased cautiously until the patient is taking as much as 200 roentgens to this enormous field in a day. Blood counts are carried out about every five days and, in the absence of a contraindication, treatment is continued until a dose of 1,000 roentgens has been applied to each field over a period of about a month. The blood counts show a steady fall in leukocytes with the incidence on the lymphocytes as the treatment progresses, but it is only when the total leukocyte count falls to 1,200 or the lymphocytes to 200 that this is regarded as a contraindication to the continuance of the treatment. In the abdominal bath the upper limit is at the level of the ensiform cartilage and the lower includes the groin gland areas. Treatment is begun with twenty-five surface roentgens and may be increased gradually to about 150 surface roentgens. The total dosage is, as in the thoracic bath, about 1,000 surface roentgens to each field. In the trunk bath the field extends from the mandible down to below the groin gland areas, the limbs being very carefully protected. Treatment is begun with twenty surface roentgen doses and increased to as much as 125 surface roentgens daily. Total dosage is from 600 to 750 surface roentgens to each field. In addition to the fall in leukocytes, hemorrhages and petechiae on the limbs are indications for the immediate cessation of the treatment. Recovery can occur after the stage of hemorrhages and petechiae has been reached. Results are good in the thoracic and abdominal baths, in the sense that superficial and deep masses in the regions treated disappear, cachexia is relieved and the patient returns often to an apparently normal state of health and to his work. The most remarkable results are obtained in the trunk baths. Of seven consecutive patients

were given trunk baths in 1932, 1933 and 1934, three are alive and well, some having had intermediate treatment. Two died as a direct result of the treatment. Five had lymphadenoma, one a seminoma and one a sensitive ovarian tumor. These methods of treatment, in the case of the regional baths, are safe and valuable, but the trunk bath is dangerous and still under trial. Its use is justified only in hopeless cases.

The Gastric Lesion in Pernicious Anemia.—Magnus and Ungley examined the stomach in seven cases of pernicious anemia. Macroscopically the upper two thirds of the stomach showed such atrophy that this area was reduced to the thinness of parchment. At the junction of the body with the pyloric mucosa, however, there was a transition, usually abrupt, to the normal thickness of the wall of the stomach and this was maintained throughout the whole of the pyloric antrum and duodenum. The mucosal surface in the upper atrophic region was flattened and a normal gastric mucosa could no longer be seen, while in the pyloric region the mucosal surface was normal. These appearances are so characteristic that it is possible to recognize the stomach from a case of pernicious anemia by naked-eye examination. Microscopic examination confirmed the naked-eye distribution of the atrophy. In the mucosal region there was atrophy involving all the coats of the wall of the stomach. In the mucosa all that remained was the surface epithelium and a few scattered glands, while the specialized oxyntic and peptic cells disappeared entirely. Yet there was absence of fibrosis, cellular infiltration, obliterative endarteritis or other evidence of past inflammation; there was a corresponding absence of fibrosis in the submucosa and subserosa. The muscular coat showed atrophy, but here also fibrosis was absent. In all seven stomachs there was no suggestion of atrophy or of an inflammatory lesion in the pyloric or duodenal mucosa; Brunner's glands also showed no abnormality. It has been generally assumed that the gastric lesion in pernicious

anemia is the end result of an inflammatory gastritis, but their material indicates to the authors that this is not so. The gastric lesion is to be regarded as an atrophic process, the cause of which is not yet known but which may be the end result of some endocrine or nutritional deficiency or may even be congenital. From its nature it is unlikely that regeneration to a normal gastric mucosa ever occurs.

Surgical Treatment of Bell's Palsy.—Morris believes that a period of from six weeks to two months is the limit of time a case of Bell's palsy should be treated expectantly, when there is no evidence of voluntary movement of the facial muscles. If faradic response is lost, or the reaction of degeneration can be obtained before this, the sooner decompression of the nerve is carried out the more chance has the patient of complete recovery. When a paralysis has been treated expectantly with some recovery and then comes to a standstill, further improvement may be anticipated by decompression and, in the cases of longer duration, introduction of an "inlaid graft," which by chemotaxis will stimulate the existing active fibers of the nerve. The operation should not be attempted in any case in which the presence of muscular tissue cannot be demonstrated. In the twelve cases discussed there has been recovery, complete in the early ones and partial in the long-standing ones.

Copper Sulfate Treatment of Tropical Ulcer.—Gunther states that tropical ulcer and New Guinea mouth disease differ only as to the site of occurrence; each is fundamentally due to food deficiency, each presents a foul, sloughing ulcer, from each a spirochete and a fusiform bacillus can be isolated and each responds to the same form of treatment. The two conditions are almost entirely confined to natives. The first essential in general treatment is a diet rich in vitamins. The patients are not given rice but receive abundance of fresh vegetables; an autolyzed yeast preparation and cod liver oil are added. In local treatment copper sulfate acts with such rapidity in comparison with other forms of treatment that it can be regarded as specific. It is best used as a solution of 1 in 150 approximately. It is applied as a wet compress to ulcers and employed as a mouth wash in New Guinea mouth disease and as a continuous bath for tropical ulcer. No ill effects have been observed from its use.

*Kidney Growths in the Upper Pole: An Early Diagnostic Sign. R. C. Begg.—p. 131.

Kidney Tumors in the Upper Pole.—Begg states that dilatation of the subcostal vein alone is an early sign that tumor of the upper pole exists. This dilatation arises from the peculiar anatomic position of that structure. The subcostal vein passes in front of the quadratus lying between it and the kidney. It is thus a posterior relation of the upper part of the organ. The sign is thus the more valuable, as tumors of the upper pole may reach a considerable size before either they or the lower

pole of the kidney itself are palpable. This dilatation may be little marked and may be perceptible only by comparison with the other side. It is most obvious after the patient has been standing or walking for a while before the examination. It appears either in the form of a linear vein like a blue pencil mark passing obliquely upward and outward between the anterior superior spine of the ilium and the umbilicus—nearer the former than the latter—or as a distinct tracery of small veins at the outer border of the rectus muscle 2 inches above the level of the upper margin of the symphysis pubis. If distinct unilateral dilatation confined to the radicles of the subcostal vein is seen, pathologic changes of the upper pole of the corresponding kidney must be considered and investigation carried out. When renal tumor is suspected because of hematuria or bony metastases of unknown origin, the sign helps to indicate the side affected and should be taken into account when the pyelogram is inconclusive.

Tuberculosis in American Colleges.—Long states that studies continued over a decade indicate that the proportion of elementary and high school children positive to the tuberculin test is steadily falling. In the less crowded communities the drop is more striking than in large, congested cities. The incidence in rural communities is generally significantly lower than in urban areas, and differences within the same community are always found corresponding to the economic level. Important tuberculous disease is first encountered in an appreciable extent in high school students, where the combined incidence of latent and manifest disease varies from 1.5 to nearly 3 per cent, being higher among girls. Important disease demanding care occurs in from 0.5 to 1 per cent of these children. Active programs for the early detection and control of tuberculosis in schools now operate throughout the country. The basic principles of these programs are mass tuberculin testing, x-ray examination of the positive reactors and provision of suitable care for those found to have lesions. In the colleges about six students per thousand have tuberculosis of the adult type. The average incidence of infection for the country as a whole is from 30 to 35 per cent. A marked variation occurs geographically, students from the great central portion of the country having a relatively low incidence. Tuberculosis is recognized as the most serious disease of the college period yet as insidious in onset, requiring routine mass-measures for its detection. Most of the lesions now discovered are in the minimal stage. Students of medicine and nursing are now known to be subject to a special hazard. The danger for medical students seems greatest during the third and fourth, or clinical, years, suggesting that tuberculosis acquired in the medical school is usually exogenous. Most nurses who are tuberculin negative on beginning training become positive to tuberculin during their course. The incidence of clinical tuberculosis is also proportionately high as compared with other professional or working groups at the same age, both during the period of training and in the first years after qualification.

Icterus Produced by Cholelithiasis.—Brulé points out that, whereas the majority of the infectious forms of icterus are diseases of the liver and not of the biliary tract, there are cases in which an inflammatory obstruction of the choledochus is the causal factor. An essential symptom of this form of icterus is a considerable enlargement of the liver. This hepatomegaly is often accompanied by splenomegaly, but there is no sign of enlargement of the gallbladder. The author points out further that the icterus produced by cholelithiasis is observed especially in persons between 25 and 30 years of age, but it has been observed also in children and in aged persons. It seems to be especially frequent in males. The onset may resemble that of catarrhal icterus with a precitric period of gastrointestinal disturbances, with pains in the right hypochondrium and perhaps with articular and muscular pains; but it may also appear insidiously, like cancer of the pancreas. The duration varies; whereas the primary cholelithiasis yields quickly to duodenal tubage, in the majority of patients, who have been icteric long before the first tubage, the disorder remains for a long time. After commenting on the origin and reporting a case, the author emphasizes that the icterus by cholelithiasis is much less frequent than the icterus by hepatitis. Nevertheless, in spite of the relative rarity, it is important that the possibility of a cholelithiasis be taken into consideration in cases of icterus that are accompanied by progressive hepatomegaly, for treatment may be effected rapidly by means of duodenal tubage. The author believes with F. Ramond that the intraduodenal administration of solution of magnesium sulfate or of olive oil (he always employs the two successively) provokes an aspiration by successive contraction and relaxation of the duodenum, thus draining the choledochus. In the cases in which treatment is begun early a single tubage may be adequate, but in cases of greater duration repetitions may be necessary.

Transfusions of Placental Blood.—Keller and Limpach point out that in obstetrics blood transfusion is the method of choice in the treatment of the profuse hemorrhages. In gynecology they utilize its hemostatic effect in metrorrhagia and in the oozing of blood after operation. Leriche demonstrated that blood transfusions are helpful in the prophylaxis of post-operative complications and that transfused patients are better able to cope with the risks involved in all interventions. Since it was difficult to secure donors, they resorted to the use of placental blood, which they were able to obtain in their obstetric service. Placental blood has a high content in erythrocytes, leukocytes and hemoglobin. Of course the placental blood should be derived from healthy parturient women. After the child is born, the umbilical cord is grasped with a sterile forceps, cut and carefully disinfected. The first few drops of blood are placed in a test tube containing a solution of potassium oxalate (potassium oxalate, sodium chloride and water). This mixture is centrifuged and conserved to test the compatibility. Then the placental blood is collected in a glass container, previously rinsed with 5 cc. of a 10 per cent solution of sodium citrate. While the blood is flowing, the container is shaken mildly. The average amount of placental blood obtained after each delivery is from 60 to 90 Gm. The

blood is stored at a temperature of 2 C. and is utilized within thirty-six hours. From 4 to 5 cc. of blood is withdrawn from the patient who is to receive the transfusion. Following centrifugation, two drops of the serum of the recipient is mixed with one drop of the donor's blood that had been collected in the test tube with the sodium citrate. The mixture is observed for from five to ten minutes and the macroscopic observation is followed by microscopic control. If there is no sign of agglutination, the transfusion can be made. The container with the blood is placed for a time in a water bath at 38 C. Then the blood is filtered through three thicknesses of sterile gauze into a graduated cylinder that has been rinsed with physiologic solution. Then the blood is introduced into the vein of the recipient. This method of indirect transfusion has proved entirely satisfactory.

Estrogen in Undesirable Lactation.—Adrian resorted to the treatment with estrogen, with the exclusion of all other therapeutic measures, in all cases in which an inhibiting treatment of the mammary secretion was justified, such as in cases of pulmonary tuberculosis, in cardiac defects of the mother, in stillbirth or in early death of the infant. In some cases three injections of 20,000 international units are required; in other cases a single injection of this quantity is sufficient. This treatment proved successful in 57 per cent of 100 cases. In the other 43 per cent the results were insufficient in that the secretion with expression of the breast persisted after the treatment. However, the result was nevertheless considerable in that the painful tension in the breasts, as well as the spontaneous secretion, ceased.

Determination of Estrogenic Hormone in Women.—Durupt shows that the present methods of determination of the estrogenic hormone in blood and urine are based on the phenomenon of Allen and Doisy; namely, the production of estrus in castrated rats. Estrus is ascertained in the vaginal secretion, which reveals the presence of keratinized cells, owing to the desquamation of the uterine mucosa. The smallest quantity of hormone capable of causing the appearance of keratinized cells in the vaginal fluid of the castrated rat represents a rat unit of the estrogenic substance. The technic appears simple but in reality is complex and inexact. Since the response of different races of rats differs, it is essential to use one identical race stabilized by consanguinity. Individual sensitivity of the animals plays a part. This is influenced by the time of castration, by the food and so on. Reading the results of the Allen-Doisy test and the method of extraction are further sources of error. In his investigations the author employed instead of the inexact rat or mouse units the international unit, the weight of which corresponds to 0.1 microgram. As test animal he uses the impuberal mouse as is done in the Doisy-Curtis test. He found that the test of Doisy and Curtis is as sensitive as the Allen-Doisy test that is made on castrated mice and five times more sensitive than that made on castrated rats. It appears with aqueous solutions in three daily injections of 0.5 cc. containing 0.17 microgram of estrogen and with oily solutions of 0.25 cc. injected at once and containing 0.25 microgram. The test is done by simply opening the vagina. The presence of oozing with whatever cellular desquamation exceeds the threshold of reaction. To compare the results obtained with the test of Doisy and Curtis with those recorded in the author's table it is necessary that the condition under which the determinations are made are similar to those adopted by him, that is to say, employing aqueous solutions, three equal injections at twenty-four hour intervals with a quantity of 0.5 cc. each and with an oily solvent employing 0.25 cc. and only a single injection.

Diagnostic Value of Capillaroscopy in Pregnancy.—Following a review of the literature on the condition of the capillaries during pregnancy and puerperal sepsis, Melbard reports his studies comprising 358 examinations, of which 118 were made on sixty-seven pregnant women between the second and ninth months. Of these, thirty-four were examined also during the puerperal period, which took a normal course. The 240 other examinations were made on patients with puerperal complications. Some of these were under observation for three months, the majority for from one and a half to two months. During this time they were subjected to capillaroscopy up to nine times. In summarizing, the author says an augmentation

of the capillaries can be found in two thirds of all pregnant women. It may be clearly visible from the second month of the pregnancy and may persist until delivery. The augmentation of the number of capillary loops became visible in 16 per cent of the cases examined by the author. The morphology of the capillaries is influenced by the sympathetic nervous system, by the endocrine system and by the products of the increased metabolism which is characteristic of the organism during pregnancy. However, it is necessary to take into consideration also diseases of the heart, of the kidneys, sclerotic processes and so on. In puerperal sepsis the capillary alterations are not merely of a functional character but in the majority of cases are of an anatomic nature. These anatomic alterations of the capillary system may be designated as peripheral endarteritis. In the grave septic puerperal complications the capillaries often remain dilated until general improvement of the patient occurs. The morphology as well as the functional aspects of the capillaries have considerable diagnostic and prognostic value in pregnancy as well as in puerperal sepsis.

Ocular Manifestations of Malignant Endocarditis.—Bonnet and Bonamour say that malignant endocarditis with slow evolution, appearing as a primary septicemia grafted on old valvular lesions, can manifest itself in exceptional cases by a sudden dramatic visual disturbance, a unilateral amaurosis caused by embolism of the central artery of the retina. In the evolution of malignant endocarditis, when attention is not called to the eye by any functional trouble, the systematic examination of the fundus reveals in 40 per cent of the cases retinal changes of great value for the diagnosis of the disease. The retinitis of Roth—hemorrhages with white centers, roundish or oval, of navicular form, clearly outlined, and white spots without hemorrhage—seemingly represent the most characteristic change in the chronic form of malignant endocarditis with slow evolution. These hemorrhages appear rapidly in several hours, becoming obliterated and reappearing in other places. These are probably the foci of necrosis limited to the retina at the level of the microbic colonies disseminated by the blood stream in the layer of the nervous fibers. More massive hemorrhages with white central foci may also be observed in front of the vessels in a diffuse edematous process of the retina. It is not exceptional to observe forms which by their association with the changes in the uveal tract and their inflammatory character permit septic retinitis to be considered as an attenuated form of metastatic ophthalmia. The observation of retinal changes remains, although less than was formerly asserted by Litten, a sign of an unfavorable prognosis, quite often the indication of an early fatal outcome.

Histamine as Chemical Transmitter.—Gajdos says that among the numerous physiopathologic problems raised by the research on histamine there are two which are of especial practical interest: the analgesic action of this substance and its role in the hyperergic diseases. The author reviews the observations of other investigators on the action of histamine and cites his own studies. He arrives at the conclusion that histamine can be considered as a specific chemical intermediary between the variability of causes and the identity of the reactions of the organism. Thus histamine constitutes one of those substances the introduction of which into a morbid process, between the cause and the effect, gives to the pathogenesis a new orientation which can perhaps be compared with the notion of chemical transmitters in normal physiology; namely, with epinephrine as the transmitter of sympathetic excitation and with choline as transmitter of parasympathetic excitation.

- Existence of Substance which Stimulates Permeability of Tissues (R Factor) in Placenta, Amniotic Fluid, Blood of Mother and Fetus and Urine of Pregnant Women. G. Lucchetti.—p. 110.

Hypochromic Anemia in Pregnancy.—Caffaratto states that the number of erythrocytes and the amount of hemoglobin are diminished in normal pregnancy, especially during the last months. When the changes of the crisis of the blood are slight, they constitute a simple form of physiologic hydremic anemia which may evolve to hypochromic anemia. Hypochromic anemia in pregnancy originates mainly in the following factors: the derivation of iron from the body by the fetus, hypochlorhydria (in grave cases), a deficient supply of iron in food and an increased elimination of iron through the feces and urine. Common hypochromic anemia in pregnancy is more frequent in women who are in moderate economic circumstances than in those of better living conditions. Administration of small doses of iron with the ordinary diet or a diet which contains a sufficient quantity of iron to supply the patient with a daily amount of about 0.04 Gm. is of value in preventing hypochromic anemia. The preventive treatment should be administered from the fourth month of pregnancy up to its completion. In hypochromic anemia it is advisable to give iron in large doses and a diet rich in iron but well balanced in proteins, fats and carbohydrates. The following daily doses of iron are in general use: from 2 to 10 Gm. of reduced iron, 1 to 3 Gm. of iron sulfate, 6 Gm. of iron and ammonium citrate, 2 to 3 Gm. of iron protoxalate or 0.6 to 1.6 Gm. of iron hydrochloride. A diet with predominance of proteins over carbohydrates and fats lowers the amount of hemoglobin, which remains unchanged when fats are in predominance and increases when carbohydrates predominate. The variations for assimilation of iron from food depend on the quality of iron and on the individual capacity of absorption. Iron contained in carbohydrates is more easily assimilated than that of fats and proteins.

- Hyperplastic Follicular Lymphopathy. A. Fieschi.—p. 145.

Morphology of Erythrocytes and Structure of Blood.—Triolo studied the blood in the blood vessels in the mesentery of guinea pigs and also in emulsions of beef fat in oil of almonds, lipoids, liquids of fixation and bile. In all cases he found that erythrocytes are spheres entirely filled with plasma which roll through the blood vessels in close contact. They modify their form in passing through the capillaries but regain it as soon as they have passed. Plasma in the free state does not exist in the vessels unless there are discoid or bell-like erythrocytes, which shows that discoid and bell-like erythrocytes are altered erythrocytes which eliminate plasma. Coagulation takes place by elimination of plasma by trauma on the erythrocytes. The separation of blood into blood serum and clot can be prevented for more than three months when trauma, during the process of collecting blood, is prevented.

- Action of Staphylococci Anatoxin Applied Locally on Infected Wounds and Inflammatory Foci. C. Tangari.—p. 343.

Ucko's Liver Function Test in Diseases of the Skin.—Bronzini states that there is a relation between dysfunction of the liver and disease of the skin, especially eczema. The author describes the clinical picture of migration, congestion, acute yellow atrophy, suppuration, cirrhosis, cancer, echinococcosis and syphilis of the liver and discusses the diagnostic value of

certain tests for function of the liver with especial reference to Ucko's test. The technic of Ucko's test has been described in the literature and recently in an abstract in THE JOURNAL (April 9, p. 1238). He obtained positive results of Ucko's test for function of the liver in thirty-two of 100 patients with various clinical forms of eczema. The more serious the cutaneous disease the more intense the results of the test. A treatment administered with the aim of controlling the disturbance of the liver induced great improvement or complete recovery of eczema in the cases reported by the author. He shows the advisability of performing Ucko's test in eczema and of administering a treatment in accordance with the results of the test.

- *Method for Rapid Lowering of Azotemia of Mean Intensity. M. Pompili.—p. 385.

Method for Rapid Lowering of Azotemia.—Pompili emphasizes the diagnostic and prognostic significance of azotemia in the course of surgical diseases of the urinary tract. The method described by the author consists in the administration of a low protein diet with abstinence from meat and eggs but liberal amounts of greens and fruit, raw liver and small quantities of milk and diuretic beverages. If tests show dysfunction of the liver, it is advisable to give intramuscular injections of from 0.1 to 0.2 Gm. of liver extract in solution or intravenous injections of sodium dehydrocholate. The patient receives also 10 or 15 units daily of insulin, which is given fifteen minutes after administration of a 50 per cent dextrose solution by mouth. The solution of dextrose contains 2 Gm. of dextrose for each unit of insulin that the patient takes. The patient also receives, each morning, 100 cc. of water or milk in which two tablets of a preparation containing magnesium fluoride, iodide, bromide and chloride are dissolved. The treatment is administered for four or five days during which hyperazotemia is lowered to less than half the previous value. The treatment is then discontinued and a few days are allowed to elapse during which time azotemia continues to decline. During this time surgical interventions, especially on the urinary tract, can be performed with a better prognosis than before the treatment when azotemia was present. The author does not give detailed doses for the treatment.

Lipasic Power in Pulmonary Tuberculosis.—Costantini and Tosi discuss the subject of relation between lipases and pulmonary tuberculosis. According to them, the tubercle bacillus induces a general organic reaction with consequent production of lipases and proteolytic enzymes. The authors review the literature and find that the immunity or increased resistance of certain animals to tuberculosis depends on the intensity of the lipolytic power of the blood or of certain tissues. The importance of the presence of lipases in the blood, the lymph or certain tissues as lysing agents of tubercle bacilli is obvious. The normal lung has a lipolytic ferment the amount of which diminishes in pulmonary tuberculosis. The amount of lipases and the lipolytic power of the blood are diminished in tuberculosis with increasing or diminishing oscillations which are related to the improvement or aggravation of the disease. The mechanism of the lipolytic phenomenon of tubercle bacilli is not clear. The actual aim in controlling pulmonary tuberculosis is to stimulate the body to the production of new enzymes, especially those which may have a direct action on the capsule. The administration of fats with the diet failed. The authors succeeded in increasing the lipolytic power of the blood of rabbits by administering beeswax to the animals.

Hydrochloric Acid in Tuberculosis.—Iraci determined the gastric secretion of hydrochloric acid in twenty-five patients suffering from tuberculosis. He concludes that hyperchlor-

hydria or hypochlorhydria depend on the prevalence of a vagal or sympathetic innervation. The tuberculous toxins do not have a direct action on the gastric secretion. They aggravate, however, the condition of latent rupture of the vagosympathetic equilibrium that exists in pulmonary tuberculosis. The disease develops more frequently in patients with constitutional predominance of the sympathetic innervation than in those with a predominance of the vagal innervation. In the advanced stages of pulmonary tuberculosis the sympathetic innervation predominates over the vagal and there is hypochlorhydria. In disturbances of the gastric secretion in patients suffering from pulmonary tuberculosis it is advisable to give a combined treatment in order to control the changes of the gastric secretion and also of the sympathetic nervous system.

Islands of Langerhans and Vitamins B₁ and C.—Mosonyi and Aszódi cite earlier animal experiments in which they were able to show that the intravenous administration of vitamins B₁ and C leads to a greater secretion of insulin into the blood stream of dogs. The vagotropic action of the two vitamins has an important part. The results of animal experiments induced the authors to try the treatment in human subjects with and without diabetes mellitus. They found that in healthy subjects the intravenous administration of vitamins B₁ and C results in the secretion of larger quantities of insulin and in a reduction in the blood sugar. The same effects could be obtained in the majority of patients with diabetes mellitus. By the prolonged, partly parenteral and partly oral administration of both vitamins (B₁ and C) it was possible to produce a considerable increase in the tolerance for carbohydrates, and insulin could often, at least temporarily, be dispensed with in diabetic patients.

*Influence of L-Ascorbic Acid (Vitamin C) on Diabetes Mellitus. M. Oshima, T. Terashima and Y. Matsutani.—p. 262.

Failures of Vitamin C Therapy.—Walther reports cases of hemorrhagic diathesis in which treatment with vitamin C was without effect. In three cases of progressive thrombopenia, large doses of vitamin C failed to arrest the disorder. The author thinks that in the first of these cases a deficient resorption in the oral administration of the vitamin was the cause of the failure and that irreparable damage to the hemopoietic system was responsible in the other two. In four patients with hematuria resulting from hemophilia and glomerular nephritis, respectively, daily intravenous injections of from 100 to 500 mg. of vitamin C, for a period of from six to fourteen days remained ineffective. In three cases of essential thrombopenia the vitamin C therapy not only failed but a further reduction of thrombocytes also was observed in two of these patients. In one of them the number of thrombocytes increased again when the daily intravenous injections of vitamin C were discontinued. In one patient mild bronchopneumonia developed during prolonged parenteral vitamin C therapy. The question is discussed whether this patient had a hypersensitivity to cevitic acid or whether there was a relative deficiency of the epithelial protective vitamin A as a result of excessive dosage of vitamin C.

Influence of Cevitic Acid on Diabetes Mellitus.—Oshima and his associates studied the influence of cevitic acid on the sugar content of the blood and urine in normal

persons and in patients with diabetes mellitus. They found that in healthy subjects the intravenous injection of 300 mg. of cevitic acid did not influence the blood sugar curve. In diabetic patients, however, the injection of 300 mg. of cevitic acid produced nearly always a reduction of the sugar content of blood and urine. The authors report four cases of diabetic mellitus in which they resorted to treatment with cevitic acid. In one of them the blood sugar was comparatively low and the urine was free from sugar. In this mild case of diabetes the effect of the cevitic acid was not so noticeable as in the other cases.

*Diagnostic Value of Cystography in Placenta Praevia. K. Jabłoński and E. Meisels.—p. 532.

Implantation of Ureters into Rectum.—Nürnberger describes the histories of two cases of vesicovaginal fistulas in which he resorted to implantation of the ureters into the rectum according to the Coffey-Mayo method. Both patients died. Discussing these cases, the author directs attention to animal experiment by Reimers and to clinical observations made by Mikulicz-Radecki and Krauspe, which indicate that the implantation of the ureters into the rectum not only is likely to aggravate an existing infection but may also prepare the way for new ascending infections of the urinary tract. He concludes that operations for vesicovaginal fistulas always involve risks, which are especially great in the rectal implantation of the ureters.

Diagnostic Value of Cystography in Placenta Praevia.—Jabłoński and Meisels report observations with the cystographic method which Ude and Urner recommended for the diagnosis of placenta praevia. The method is suited especially for the cases in which the fetus is in the vertex position. Ude and Urner maintained that the distance between the lower outline of the fetal cranium and the contrast shadow of the bladder measures normally at the most 1 cm. and that this distance is taken up by the thickness of the wall of the urinary bladder, of the uterine wall and of the fetal scalp. Jabłoński and Meisels, however, assert that the distance is dependent on the following factors: (1) the degree of dilatation of the lower uterine segment and the lifting of the bladder connected with this and (2) the lowering of the fetal head. This explains why, between the seventh and tenth months of pregnancy, the distance becomes constantly smaller so that during the last weeks of pregnancy the outline of the head almost touches the shadow of the bladder. However, if a body is interposed between the fetal head and the uterine wall, such as for instance the placenta or a myoma, the distance is in excess of 1 cm. The cystography is done in the following manner: After evacuation of the bladder by means of a catheter, 40 cc. of contrast fluid (a 12.5 per cent solution of sodium iodide or another contrast substance) is introduced into the bladder. After withdrawal of the catheter, a ventrodorsal roentgenoscopy is made, with the patient in the reclining position and the central ray directed toward the rim of the symphysis. The authors made this test on thirty pregnant women. In sixteen of them hemorrhages had occurred during the second half of pregnancy and the other fourteen cases served as controls. They found that this roentgenologic method permits the detection or exclusion of the placenta praevia if it is of the central or lateral type. A placenta praevia marginalis, particularly if located on the posterior uterine wall, usually cannot be determined by means of this method. Another disadvantage is that the method can be used only if the fetus is in the vertex position. However, the authors suggest that, in some cases of oblique, transverse or pelvic position, external version into the vertex position can be tried. They succeeded in accomplishing this in three cases.

 *Immediate and Late Results of Resection for Gastric Cancer. A. S. Fedoreev.—p. 139.

Results of Gastric Resection for Cancer.—Fedoreev states that, of the patients admitted to the Leningrad Onkological Institute during a period of six years because of cancer, 49 per cent were incurable, while in the succeeding four years the percentage of incurable cases amounted to 31. The total operability of the gastric cancer amounted to 9.6 per cent for the first five years and to 12.2 per cent in the succeeding five years. Operability among patients first studied in the dispensary gave an average of 27.7 per cent and that of the last four years 31.5. The incidence of gastric cancer in women was one tenth that of the incidence in men. Gastric cancer in young persons is particularly malignant and the late results are almost always unfavorable. The fact that the tumor may be palpated does not necessarily exclude its operability. In 66 per cent of 414 resections the tumor was palpable. Stricter operative indications, improvement in technic and careful preparation of the stomach through lavage with dilute hydrochloric acid solution brought about considerable improvement in the results and lowered the mortality for uncomplicated resections from 40 to 16 per cent. Further improvement in the immediate results is to be looked for principally along lines of limiting the operative indications by a medical staff with a sufficient clinical and technical experience. The author would particularly limit the indications for the so-called extensive resections involving some of the neighboring organs, since half of these patients do not survive the operation while the remainder succumb to recurrences within the first two years and but rarely survive three years. Resection of the stomach with a segment of the transverse colon gives an immediate mortality of 70 per cent, while those who survive live from one to two years. A five year survival is quite exceptional. This operation therefore is indicated in exceptional cases in which the neoplasm is sharply delimited. In such operations it is obligatory to bring out the end of the afferent loop of the colon in the form of an artificial anus or to bring out both ends and later perform an ilcosigmoidostomy.

 *Remarks on Clinical Observations in Frontal Intracranial Tumors. A. Torkildsen.—p. 310.
 Pancreatic Cyst: Case. A. Arnesen.—p. 326.

Alcohol Determinations in Necropsies.—Guldberg performed forty-nine legal necropsies in which determinations of alcohol were made and illustrates by examples from these cases how the tests may check and supplement the results of necropsy and other evidence produced. In four of seven cases the alcohol concentration in the stomach was found to differ from that in the blood and urine. He considers the possibility of a diffusion of alcohol from the stomach into the immediate neighborhood and points out that too high values may be obtained in specimens of blood from the heart; he advises taking blood for alcohol determinations in legal cases from places remote from the stomach. In one case the test was successfully made in the blood eleven days after death, in another in the urine seven weeks after death.

Mortality Rate in Operations for Hernia.—Harbitz's material comprises 1,046 cases of hernia in which operations were performed from 1926 to 1935. The interest centers in

the 836 cases of persons over the age of 20, 705 of whom had nonincarcerated hernias (550 inguinal, forty-seven femoral, 108 umbilical hernias, hernias of the linea alba and ventral hernias) and 131 incarcerated hernias (fifty-two inguinal, forty-nine femoral, thirty umbilical hernias, hernias of the linea alba and ventral hernias). Thrombo-embolism occurred in fourteen cases (2.8 per cent) of the nonincarcerated hernias, with a mortality of 0.14 per cent; one patient died from postoperative pneumonia and the total mortality was 0.28 per cent. In the incarcerated hernias, thrombo-embolism was seen in four cases (3 per cent), with a mortality of 0.77 per cent; there were twenty-one deaths from ileus and the total mortality was 16 per cent. Thrombo-embolism occurred in 2.87 per cent of all patients over 20. No appreciable difference appeared between the sexes, and the side operated on apparently had no significance. Nonincarcerated inguinal hernias were relatively frequent in patients of lower age. The author finds that complications of embolic kind seem especially likely to appear in femoral hernias as compared with the other two groups studied. The total frequency of thrombo-embolism in femoral hernias was 8.3 per cent, the frequency in nonincarcerated femoral hernias 10.6 per cent and, in the incarcerated, 6 per cent. More than half of the femoral hernias operated on were incarcerated and the mortality in these was 19.1 per cent.

Frontal Intracranial Tumors.—In the *Norsk Magasin for Lægevidenskapen* 99:137 (Feb.) 1938 Torkildsen reviewed data concerning 353 cases of intracranial tumor, including 154 verified cases. He now analyzes the thirty-one verified cases of tumor of the frontal lobe from this material (eighteen gliomas, six meningiomas, two abscesses, one cholesteatoma and four cases in which the expansive lesion was verified on pneumography but not classified) in eighteen men and thirteen women; all but three were over 20 years of age. The most important symptoms are discussed and all symptoms which appeared as the first three symptoms are tabulated in their chronologic order, with their duration. The most important symptoms were headaches, epilepsy, nausea and vomiting, together with loss of vision, usually a late symptom. Twenty-two patients had mental symptoms, of which dulness was the most common; these symptoms were more frequent in cases of tumor on the left side than on the right. Choked disk was seen in twenty-four cases. It appeared in all cases with vomiting and nausea, in sixteen of the eighteen cases with headache and in nine of the fourteen cases with epilepsy. There was paralysis of the facialis muscle in eighteen cases. Derangement in the sensory system appeared in six cases, in the motor system in twelve, and in two cases with homolateral hemiplegia. Examination of the spinal fluid in nineteen cases revealed definitely increased cell count in only one instance.

 *Paroxysmal Heart Block in Young Person. W. T. Andersen.—p. 250.

Paroxysmal Heart Block.—The complete atrioventricular heart block in a man aged 20 disappeared after two days' treatment with atropine. The history excluded trauma or medicinal cause. During the six days preceding the attack the patient had had increasing pain in the epigastrium and nausea, which is ascribed to an acute disorder at the cardia (esophagitis, gastritis?). Andersen considers the case one of neurogenic reflex block. He cites a case with attacks of heart block (Weiss and Ferris) believed to have been caused in a reflex way through the vagus, and another of neurogenic block (Flauma and Klima) reflected through the superior laryngeal nerve and refers to Gilchrist, who asserts that he has seen eight cases of neurogenic block. The author says that digitalis block may perhaps have a similar origin. The attacks are successfully treated with atropine, epinephrine or ephedrine. The possibility of the disorder ought to be borne in mind. It might occasionally manifest itself in operations in the neck region; preliminary treatment with atropine or ephedrine should hinder its occurrence.

MAY 28, 1938

CASE 5.—In M. S., aged 7 years (adiposogenital dystrophy due to hypothyroidism), the right testis was not felt and the left testis was not felt definitely, although some hypertrophied

tissue below the internal ring was suggestive. The penis was infantile and the scrotum was incompletely formed. This was my first case and as such the treatment was rather irregular and was prolonged over a period of four and one-half years. After six months of treatment with 10,000 rat units of antuitrin-S the right and left testes were felt definitely in the canal. At the end of treatment with 20,000 rat units of antuitrin-S in twelve months and with 37,000 rat units of follutein in fourteen months the right testis was the size of a hazel-nut and resident in the scrotum, and the left testis was of the same size in the lower part of the inguinal canal. The external genitals appeared more matured, the penis was enlarged and the scrotum was formed better. The result of treatment was positive. (Previously reported as case 4.)³

CASE 6.—In R. S., aged 9 years (nonobese, hypothyroid), the left testis was not felt and the right testis was hypoplastic in the scrotum. The scrotum was incompletely formed and the penis was small. The left testis was felt past the internal ring after one and one-half months of treatment with 11,000 rat units. After 37,840 rat units of follutein and 17,000 rat units of A. P. L. in five months, the left testis was the size of a small kidney bean and could be pulled down to the midscrotum; the right testis increased in size, and the penis and scrotum became enlarged and pubic hair appeared. The result was positive.

CASE 7.—In S. R., aged 5½ years (nonobese, hypothyroid), the right testis was not felt and the left testis was hypoplastic in the canal and could be pushed down into the scrotum. After 2,900 rat units of antuitrin-S the right testis was felt past the internal ring. After 7,300 rat units of antuitrin-S and 6,400 rat units of follutein in three months the right testis was brought down low in the canal, the left testis was increased in size and was fixed in the scrotum. The result of treatment was positive.

CASE 8.—In M. B., aged 10½ years (adiposogenital dystrophy due to hypogonadism), the left testis was not felt and the right testis was migratory; the external genitals were hypoplastic. The left testis was felt past the internal ring after 5,800 rat units was given in eighteen days. After 39,700 rat units of follutein and 31,600 rat units of A. P. L. were administered in a period of seven months, the left testis was found to be the size of a shelled hazelnut and could be pushed down to the neck of the scrotum; the right testis was the size of a shelled almond and became fixed in the scrotum; the penis was enlarged and pubic hair was present. The result of treatment was positive.

CASE 9.—In G. A., aged 11½ years (adiposogenital dystrophy due to hypothyroidism), the right testis was not felt; the left testis was hypoplastic in the scrotum. The penis was of fair size; the right portion of the scrotum was undeveloped; suprapubic hair was sparse. The patient received 47,000 rat units of A. P. L., 24,500 rat units of follutein and 7,000 rat units of antophysin, a total of 78,500 rat units in seven months. At the end of that period there was a hypertrophied mass suggestive of the testis past the right internal ring on application of pressure from above. The left testis was increased in size from that of an olive seed to that of a large walnut. The penis became quite matured, and a good crop of suprapubic hair was present. The result of treatment was questionable.

CASE 10.—In S. G., aged 7 years (nonobese, hypothyroid), the right testis was not felt. A scrotal hydrocele with a small testis behind it was found on the left side. The right testis was felt past the internal ring after 9,700 rat units was given in four months. After the administration of 24,900 rat units of antuitrin-S in six months, the apparently absent right testis was definite in the canal while the left scrotal hydrocele became more tense. The result of treatment was positive.

CASE 11.—In R. A., aged 7 years (nonobese, hypogonad [?]), the right testis was not felt. A hydrocele was noted on the right side when the patient coughed. The left testis migrated between the canal and the midscrotum; a hydrocele was also present on the left side. After eleven days of treatment with 1,000 rat units, the hydrocele and testis on the right side descended low in the canal. After 13,500 rat units of follutein in four months, both testes were noted high in the scrotum but were obscured by the tense scrotal hydroceles. Some sparse pubic hair was

present. On examination eight months after discontinuation of treatment the hydroceles were less tense, the testes were stationary in the same position and the precocious suprapubic hair had fallen out. The result of treatment was positive.

CASE 12.—In M. L., aged 8¼ years (adiposogenital dystrophy due to hypothyroidism), the right testis was not defined, although some hypertrophied tissue was palpated at the internal ring. The hypoplastic left testis migrated between the scrotum and the canal. The penis and scrotum were undeveloped. After 1,900 rat units was given in one month, the right testis was felt past the internal ring on application of pressure from above. After 36,300 rat units of follutein and 8,800 rat units of A. P. L. in ten months, two testes of equal size were palpated in the scrotum; the penis and scrotum had enlarged and some pubic hair was present. The result of treatment was positive.

COMMENT

As can be seen from the reports of these cases, prior to treatment one patient showed bilateral intra-abdominal cryptorchidism (case 5); the eleven other patients showed unilateral intra-abdominal cryptorchidism and in addition all showed hypoplasia of the external genitals, usually with hypoplasia of the presenting testicle. The age range of these patients was from 3½ years to 11½ years.

In my experience with these cases of genital maldevelopment, I found that when conditions were such as those in this series, in which no sign of a testicular mass was evident at the outset, one could not know beforehand whether the testicles could be made to descend at all or, if they could be made to descend, how much endocrine therapy would have to be administered before such testicles could be felt on digital palpation.

Examination discloses that the length of time and total dosage for treatment differed in each individual case before any apparent results were attained. Once, however, sufficient and correct amounts had been administered, the apparently absent testicles in most of the cases could be made to respond to treatment. To date descent has been initiated so that they now can be palpated below the internal ring.

While it is true that some patients required only small doses before the testicles could be palpated below the internal ring, I believe that from 4,000 to 5,000 rat units of gonadotropic substance cannot in most cases cause complete descent of testicles. Failure, therefore, for such testicles to appear or to descend after such small doses have been used is not to be considered as conclusive evidence that the cases are nonresponsive to endocrine therapy. I believe, rather, that in such cases, if endocrine therapy was continued in larger doses over more prolonged periods, many such cases would be found to be more responsive to treatment. This can be best demonstrated by case 9, in which 78,500 rat units was required in seven months before a response was evoked.

In the attempt to produce this testicular descent in patients with unilateral intra-abdominal cryptorchidism, not only was this descent provoked in most cases, as can be seen from the case reports, but stimulation of the gonads of the original presenting testicle also inevitably took place. This was evident by the increase in the size of the existing testicle and the development of the external genitals in all cases, regardless of whether or not descent of the intra-abdominal testicle could be provoked. Even in case 1 and case 4, in which no descent of the intra-abdominal testicle could be provoked, and in case 9, in which to date only a mass suggestive of testicular formation can be noted below the internal ring, marked stimulation of the external genitals nevertheless has been induced, although it is

true that this occurred only after the administration of large doses of gonadotropic factor.

I realize that, while the stimulation of the external genitals has been satisfactory in most of my cases, the testicular development is far from complete. The presence of a testicle or testicles in the inguinal canal, the state of testicular development attained to date for most of my patients, is certainly far from the desired objective; nevertheless I feel that, by continuation of proper therapy, descent probably will be further provoked. This assumption is based on the fact that in the treatment of patients who had inguinal cryptorchidism I have found that sufficient treatment administered for this condition will in most cases usually bring down these inguinal testicles and anchor them in the scrotum.

Of course it cannot be overlooked that there are exceptions and that while in most cases inguinal testicles can and probably will be made to descend there are, I have found, some cases of this kind which, when complicated by other developmental anomalies (some apparent prior to treatment, others not), will fail to respond completely to treatment, because complete descent is being impeded. This I have found true in case 11, in which complete descent is being impeded because of the existence of a marked bilateral hydrocele, present before treatment was begun. While it is true that as a consequence of treatment the hydrocele sac in case 11 did descend from the inguinal canal into the scrotum and that the originally absent testicle could be felt behind this hydrocele, nevertheless further treatment did not make the hydrocele disappear entirely. It is true that with the discontinuance of treatment the hydrocele fluid did become somewhat less, and there was some retraction of the tense processus vaginalis; nevertheless, so far (six months later) it has not disappeared. I am therefore now inclined to believe that this condition, when marked, cannot be corrected with endocrine therapy. On the whole, though, such complications are not too frequent and descent does ensue.

In the attempt to correct such conditions of marked hydrocele as existed in case 11, or in the attempt to correct other stubborn case of cryptorchidism, intensive treatment with gonadotropic substance was found to cause in a number of cases precocious production of suprapubic hair. Patient 11, who was $7\frac{1}{2}$ years of age, referred to as showing marked bilateral hydrocele, was given intensive endocrine therapy, and suprapubic hair developed precociously when treatment with 20,000 rat units within a period of ten months was administered. Testicular descent was accomplished only partially when suprapubic hair developed. The production of suprapubic hair occurred also in several other of the younger boys of this series and outside this series. This seems to have been the only apparent adverse effect that developed as a result of intensive treatment. It is significant to note that with the discontinuance of treatment the suprapubic hair in two of the cases subsequently fell out. This was found to take place in case 11 eight months after treatment for intra-abdominal cryptorchidism had been discontinued. In another patient, aged $4\frac{1}{2}$ years, not in this series, precocious pubic hair fell out three months after treatment for inguinal cryptorchidism had been discontinued. This falling out occurred even though the gonads and the external genitals remained in the same state of development as before treatment had been discontinued, with the exception that there was an abatement of the genital congestion. Whether the same

falling out occurred in the other young boys who could not be seen later or whether it will occur in other cases in the future one cannot say, but it is my belief, and it is hoped, that it is not unlikely, since it is certainly to be desired. It can be said, though, that such a falling out does not occur in boys close to puberty.⁴

However, if falling out should not take place, especially in the younger boy, this production of hair, I feel, is objectionable only in that such a growth is not expected before maturity and as such there is the possibility that this might have a psychologic effect on some of the younger boys. In the two cases already mentioned, however, no such effects were apparent.

In any event, the fact that the younger boys are so much better able and so much more likely to respond to endocrine therapy for intra-abdominal cryptorchidism when it is instituted at an early age, and the fact that the institution of this treatment at an early age may, in addition, correct the underlying glandular disturbance, lead me to state that one must risk the possible production of pubic hair and the possible but also questionable psychologic effect which might ensue in some cases. Certainly in view of the promising results attained so far in this series it is not too presumptuous to claim that there is less danger in submitting prepuberal boys to intensive endocrine treatment for intra-abdominal cryptorchidism than to submit these types to multiple operative procedures or to allow them to go untreated. The remote possibility that boys with intra-abdominal testes may respond favorably to endocrine therapy in a comparatively short time without danger of any serious consequences warrants early institution of such treatment without waiting for possible and unlikely spontaneous descent and before attempting surgical intervention which may or may not cause complete descent and which generally does not correct the underlying glandular dyscrasia.

SUMMARY AND CONCLUSIONS

Twelve prepuberal boys, eleven presenting unilateral cryptorchidism and one presenting bilateral cryptorchidism, with ages ranging from 3 years and 4 months to 11 years and 8 months, were treated for cryptorchidism with gonadotropic principle from the urine of pregnant women. Doses in most cases were large and were given intensively over extended periods.

Two of the cases in this study showed no response and therefore their treatment was discontinued. Nine other cases responded definitely as a result of the administration of varying amounts of the substance, so that finally testicles in the inguinal canal were palpated below the internal ring. The twelfth case, while not showing such definite development, did show evidence of response after a very large amount of gonadotropic substance (78,500 rat units) was given over a prolonged period (seven months) so that finally the presence of a mushy mass, suggestive of testicular formation, could be felt below the internal ring.

Several facts may be evolved from this study:

1. The amount of gonadotropic substance and the length of treatment varied; a few patients required comparatively small amounts over a short period; most, however, required much more gonadotropic substance and a longer time.

4. It might be of interest to mention that in the large number of cases of genital underdevelopment which has come within my notice when suprapubic hair was present in quantity in such boys the suprapubic hair was noted frequently to be heterologous in formation. This was also noted in boys closer to puberty in whom suprapubic hair was produced as a result of treatment with gonadotropic substance. I intend to follow up such cases to note whether or not this formation will correct itself as these boys advance in age.

2. When no developmental anomalies existed to impede descent, testicular formation could be initiated and descent into the inguinal canal could be actuated in most cases of intra-abdominal cryptorchidism with varying amounts of gonadotropic substance.

3. Although in the present series of intra-abdominal cryptorchidism complete scrotal descent and fixation is still lacking and testicles have at present reached only the inguinal canal (in case 12 the testicles are in the scrotum), my past experience with cases of inguinal cryptorchidism makes me feel that sufficient additional endocrine therapy in due time will probably produce complete descent and fixation in the scrotum in some of my cases of intra-abdominal cryptorchidism, just as it did in my cases of inguinal cryptorchidism.

4. When impediments such as marked hydrocele accompanied intra-abdominal cryptorchidism and existed before treatment, as in case 11, endocrine therapy could cause the intra-abdominal testicle to descend from the abdomen but it could not correct the hydrocele. (A contrary opinion in a previous communication, to the effect that marked hydrocele could be corrected by treatment with gonadotropic substance, must be held in abeyance until further study is made in other such cases presenting marked hydrocele.)

5. In all the cases of unilateral cryptorchidism in this series, even when descent of the intra-abdominal testicle could not be actuated, the existing hypoplastic gonad and external genitals were developed through the use of gonadotropic substance to the point of apparent normality, and even in some to the point of hypertrophy of the external genitals.

6. The only seemingly adverse effect resultant from intensive treatment was the precocious production of suprapubic hair in some of the younger boys. While this precocious production of hair was not desirable, I found that my patients did not show apparent psychologic effects or any manifestations of a precocious nature.

7. This growth was temporary in one boy aged $7\frac{1}{2}$ years of this series and in one aged $4\frac{1}{2}$ years not of this series; follow-ups show that these precocious pubic hairs had fallen out after treatment had been discontinued for several months. It can be said also that suprapubic hair once produced through treatment in the boys closer to puberty did not fall out.

8. I believe that, even at the possibility of producing precocious suprapubic hair, endocrine therapy should be instituted early in boys showing intra-abdominal cryptorchidism, because the response is much more readily attained and is much more successful in those who are younger than in those boys who are approaching or who have passed the puberal age.

9. Intensive endocrine therapy in all cases of intra-abdominal cryptorchidism should be attempted without waiting for spontaneous descent and before attempting surgical intervention; there is certainly less danger.

ADDENDUM.—Since this manuscript was written the opportunity for a check-up on several of the cases in this series presented itself and the following was noted:

In case 5 a reexamination sixteen months after discontinuation of treatment (at age $12\frac{1}{2}$ years) revealed two firm, good-sized testicles in the scrotum.

In case 11, an operation for bilateral hydrocele was successfully done two months after discontinuation of endocrine treatment. Both testicles were in the scrotum and were of good size and consistency.

In case 12, ten months after discontinuation of treatment, both testicles were still resident in the scrotum.

TREATMENT OF WOUNDS RESULTING FROM DEEP BURNS

VILRAY P. BLAIR, M.D.

AND

LOUIS T. BYARS, M.D.

ST. LOUIS

Deep burns on the average constitute the largest number and, because early adequate help is so frequently lacking, are also the most neglected of all wounds amenable to surgery. Because of this, hospitalization and the wound-dressing period are unnecessarily prolonged and often followed by months, years or possibly a lifetime of discomfort or disability pending a belated surgical repair. This and much to follow is based on a series of 340 late burns treated since 1918 in which the average time that elapsed between injury and inauguration of surgical repair was 5.1 years.¹ The aggregate period of disability in this group from the time of injury until final discharge was 2,312 years, or an average of 6.8 years. These required 1,037 repair operations, with an average treatment and observation period of 17 years per case.

Increased expenditure adds to the economic hardship, which approximates tragedy when it is the earning power of the breadwinner that is at stake, while incidentally an employer may be deprived of needed services, and somebody must pay the too often inadequate compensation specified for industrial accidents by state law.

During the first several weeks after the infliction of the injury it is unnecessary and often impossible to distinguish between partial and full thickness destruction of the skin, but areas of both degrees are commonly present in almost every extensive burn. The primary consideration during this early period, and possibly for months later, is the immediate problem of saving life and of fending the vital organs and nervous balance. The greatest help will come from controlling pain, worry and infection. This most critical time having been successfully bridged, active steps for surgical repair are in order, and, if carried out judiciously in accordance with the needs and condition of the patient, these should from the first facilitate rather than prejudice the earlier objectives enumerated.

To the general practitioner, who as a rule first sees the isolated major burns and who bears the brunt of responsibility during that most trying and difficult period, should be given the credit of a life saved when the patient survives until active surgical repair can be safely undertaken. He is the unsung hero of the catastrophe and for him both respect and admiration are due. However, our observation of the cases cited rather forced the conclusion that opportunities for early repair had not been adequately met in the great majority of instances; this is commonly due to the lack of realization either that what was a burn has changed to a granulating wound or that the closure of this residual wound could be materially hastened by appropriate surgical attention. Either leads to the continuation of a simple dressing treatment long after active surgical repair could very advantageously have been done.

1. Of these, 290 were patients treated in the Plastic Surgery Service in Barnes, St. Louis Children's, and St. Louis Mullamphy hospitals, 17 which are added, through the courtesy of Dr. J. B. Brown, fifty of his own patients treated at the St. Louis Shriners' Hospital for Children.

On the depth of the extensive burn will largely depend the amount of time and the kind of effort to be expended on the repair. In second degree burns, at least, scattered deep-lying islands of epithelium will survive from which rather prompt spontaneous coverage will occur with relatively little deep scarring. In these as in any other cases of destruction of the superficial epithelium, regardless of cause, there is no essential relationship between healing time and size of the defect, and, provided the area remains clean, this kind of healing is not greatly influenced by the type of treatment employed. On the other hand, after total destruction of the skin the manner and course of healing are quite different. Here spontaneous repair is of much later occurrence and is accomplished by three distinct but somewhat overlapping processes: First, the raw surface is gradually covered by granulations; second, the deeper and older layer of these granulations takes on the character of contracting scar, which draws in the surrounding skin and superficial fascia, thus lessening the actual surface area to be repaired; third, after some days, weeks or months, earlier under proper treatment, epithelization of the remaining raw surface starts with a visible ingrowth of the surrounding skin, and perhaps from scattered epithelial remnants. Putting it another way, the spontaneous coverage of a large or of a small second degree burned area, other conditions being equal, will occur in about the same length of time, just as two neighboring grain fields will produce their entire crop simultaneously, regardless of relative size.

However, given two large third degree burns of similar circumstances but of differing size, the healing time, the resulting permanent disfigurement and the disability of each will differ, and the difference will not be in direct proportion to the diameters of the two raw areas but more nearly to the square of these diameters. For instance, as a rather loose estimate, say that a defect 2 inches in its least diameter might require four weeks for complete healing; then the spontaneous healing time for a similar wound from a burn 4 inches in

the type of treatment used. Because of this, the public and many of the profession, partly as a matter of convenience and partly because of inherent virtues, have rather the habit of relying chiefly on the application of some favorite prescription or pharmaceutical and of ascribing the cure of the burn chiefly to its use. Neither this practice nor the inference will be harmful to the patient, provided some of the deeper part of the skin remains everywhere intact. However, when the foregoing or any other plan of expectant treatment is entirely relied on in the care of the less frequently

occurring large deep burn, the patient is just plain out of luck. We might cite from our series the case of a husky young workman of limited means who had been deeply burned on the thighs and legs some eighteen months previously and had been bedridden or on crutches ever since. According to the statement of the patient and of his family physician, the local treatment had from the first been chiefly the use of a widely advertised and commonly used unguent preparation containing antiseptics and emitting a strong odor, the purchase of which had cost the patient, his family and his relatives to the date of his visit here somewhat more than \$1,200. When he came to us the persisting raw surface seemed still to be about a half or a third the size of the area originally destroyed. We were able to release the contractures, and his wounds healed completely and permanently by three skin-grafting operations, each of which required ten days post-operative treatment, though with necessary preoperative care and an intervening appendectomy his total hospitalization was fifteen weeks.

The preceding comments are not pertinent to tannic acid or any other medication when used to help carry the patient or to add comfort and prevent infection preparatory to a surgical repair when the proper time arrives, but, regardless of their potential usefulness, their use may be susceptible to costly abuse. The application of a chemical or drug in the treatment of a deep burn can at best constitute but one element of a rather intricate surgical procedure. Some of the worst conditions we encounter of late wounds resulting from burns have come from the misuse of a coagulant, usually tannic acid, without proper technic or follow-up. Unless meticulous care is given the wound resulting from a burn, the granulations early become deeply infected, as evidenced by the long persistence of rough corded or

diameter might be sixteen weeks, while one of a 12 inch diameter might not heal in 144 weeks. Examples of raw surfaces having persisted for from three to thirteen years or more after a burn are not lacking in our series. In contradistinction to the second degree burn, the time at which surgical repair of extensive third degree burns can be advantageously undertaken will in most cases be very largely influenced by the type of local and general care that was administered from the time the burn occurred.

The great majority of surface burns do not quite destroy the full thickness of the skin and, as already pointed out, healing will therefore occur spontaneously in what appears to be a reasonable time, regardless of

ridged keloid scars. With slow spontaneous healing the scar thickens, sometimes enormously, while progressive contraction and occasionally coalescing of opposed raw surfaces cause fixation and distortion, though they do decrease the raw area. Spontaneous epithelization of these maturing scars becomes progressively retarded, and the layer of this new coverage becomes quite thin and unstable, so that even after complete healing it may be repeatedly lost from diffuse hemorrhage into the deeper layers of the scar, from some local or general indisposition of the patient or from any slight trauma. The development of cancer in these old scars has occurred as late as fifty years or more after healing.

Active surgical repair of a deep burn of any considerable size should be initiated as early as practicable in the healing period and aims at permanent skin coverage of all raw surfaces done at one or several operative steps. This may be done completely by using large split grafts, or partially with scattered small grafts that serve as foci from which epithelization spreads in all directions; but either way it should be done with the least possible disturbance to an already sick patient. Usually the patient can be gotten in fair condition before this is attempted, but sometimes very simple types of grafting are done in the hope of giving a step-up to a patient who is making poor headway. The judiciously treated patient is usually easy to handle and has little fear of the dressing; this is more true with children than with adults. There are, however, a few—likely a very few—who will for some time survive the immediate shock and subsequent confusion that follow a large deep burn but will make no proper response to nursing, care of the wound, blood transfusions or skin grafting, and eventually fade out regardless of the care given. Occasionally we have, as a temporary measure, resorted to the use of homografts taken from a parent. Apparently, though we have never seen such grafts persist for more than three weeks, they seem to stimulate a more spontaneous epithelization and may be quite helpful in breaking a vicious circle that threatens to carry off the patient. If the burn were treated by primary excision of the dead tissue, grafting might be done immediately, the patient's general condition permitting, or later when the granulations and the patient become fit. When grafts are applied at this early period to an extensive raw surface no special attempt is made to correct contractions that have already occurred, but a successful take should greatly limit further distortion and enable one to measure the healing period in terms of days rather than of weeks or months or even years.

The chief point in the late correction is the liberation of false union and elimination of binding scars. This can usually be done by excising scar areas down to their deepest elastic layer, immediate application of large split thickness skin grafts, full thickness grafts or a sliding or pedicled flap. There is little to be gained by the attempt to grow skin grafts on a granulating area of years' duration without first removing the granulations and the underlying scar, which latter may be from a fourth to a half inch thick. Much late grief and multiple operations can be avoided by early successful skin coverage. By this procedure we have been able to put a breadwinner back on his job entirely healed within seven weeks after a burn that totally destroyed more than 150 square inches of skin.

In our series of surface burns, regardless of size, the total period of observation was 0.88 year as contrasted to 2.2 years of observation for the complicated structures, namely, hands, face and neck.

Properly handled, children with relatively larger losses are cared for with still greater ease. These early, sometimes makeshift, repairs may not be the final answer in the individual case but at least they will, besides shortening the convalescence, avoiding much suffering and conserving the nervous balance, very much simplify the final restoration and may prevent permanent incurable disabilities. Most important of all is the proper early care and coverage of deep burns of the back of the hand and fingers. Here the tendons and joint capsules lie almost immediately beneath the skin. Few hands that have been allowed to heal spontaneously, having remained uncovered for months or having been allowed to rest in full extension or with the weight of the flexed hand resting on the tips of the fingers, can ever be restored to anything like normal usefulness.

GONOCOCCIC MENINGITIS

SARA E. BRANHAM, M.D.

REGINALD H. MITCHELL, M.D.

AND

WILLIAM BRAININ, M.D.

WASHINGTON, D. C.

Twenty-seven cases of meningitis supposedly due to the gonococcus, reported before 1909, have been reviewed by Henderson and Ritchie.¹ Bradford and Kelley² have summarized twenty cases reported since that time and added another which they themselves encountered. Strumia and Kohlhas³ have cited thirty-eight reports. All these authors have pointed out that proof of the identity of the causal organism with the gonococcus has not been offered in all cases and that a few of the diagnoses were made on circumstantial evidence. Most of the reported cases fall roughly into two groups: meningitis in adults accompanying or following gonococcal infection of the genital tract, and meningitis in newborn infants following infection at birth. In an occasional instance the meningitis followed a septicemia without any other apparent focus of gonococcal infection.

The National Institute of Health at Washington, D. C., has for several years past been making a special study of meningococcal infections and has received a large number of cultures taken in such cases for identification and typing. Ten of the 500 cultures received to be typed as meningococci during the past two years have been found to be gonococci. One of these cases is of such unusual interest that a report of it seems definitely indicated. It represents a simple, uncomplicated primary meningitis without any other focus of gonococcal infection and with a history in which there was, so far as could be determined, no known opportunity for infection.

REPORT OF CASE

History.—B. M., a white girl, aged 16, well nourished and well developed, felt perfectly well until Sept. 8, 1937, when a headache and a feeling of lassitude and drowsiness developed. The headache became more pronounced and the next day it was accompanied by backache and stiffness of the neck and legs. She vomited once. Her family physician (W. B.) was called September 10, the third day of the illness. At this time she had a temperature of 103 F. (oral) and a pulse rate of 96. There was marked stiffness of the neck, and both the Kernig and the Brudzinski sign were positive. The knee jerks were somewhat exaggerated. Aside from these manifestations the physical examination was negative.

A spinal tap was done and the spinal fluid was found to be very cloudy and under markedly increased pressure. About 45 cc. was withdrawn and 30 cc. of polyvalent antimeningococcus serum was given intraspinally. The patient was then taken to the Gallinger Hospital, where a complete physical examination confirmed the observations of her family physician earlier in the day. The cell count of the spinal fluid was 6,100, with 95 per cent polymorphonuclear leukocytes. The patient was acutely ill but quite rational and cooperative and not especially toxic.

Vaginal smears made on admission were negative for gram-negative cocci.

A cutaneous test revealed a marked sensitivity to horse serum, so it was decided (R. H. M.) not to give more antimeningococcus serum but to treat the patient with sulfanilamide alone. She was given 50 grains (3.2 Gm.) on admission and 20 grains (1.3 Gm.) every four hours for three days, 15 grains (1 Gm.) four times on the fourth day, and 10 grains (0.6 Gm.) four times for the next five days. Beginning with the day after admission (September 11) she was given 30 cc. of an aqueous solution of 1 per cent sulfanilamide intraspinally daily for four days. She received a total of 620 grains (40 Gm.) of sulfanilamide by mouth during eleven days and 105 cc. of 1 per cent sulfanilamide intraspinally during four days.

The temperature was 103 F. on admission and the next day but it then dropped to normal and remained there. The cell counts of the spinal fluid on the first five days of hospitalization were respectively 6,100, 2,000, 1,200, 310 and 170, after which time it was perfectly clear in appearance and pressure was normal. Intracellular gram-negative diplococci were found in the first three samples but in none thereafter. A preliminary diagnosis of meningococcic meningitis was made.

On the ninth day some urticaria and slight swelling of the hands and feet developed. These did not subside immediately after the administration of epinephrine, and there was some question as to whether this rash represented a serum reaction to the one 30 cc. dose of antimeningococcus serum or whether it was due to the sulfanilamide.

Recovery was rapid and uneventful. She sat up the twelfth day after admission to the hospital and was discharged on the sixteenth day (September 26).

The patient was nearly well before the identification of the causal organism as a gonococcus seemed certain. Its similarity to the gonococcus was evident much earlier, but there was nothing in the history to suggest its presence. There was no sign or history of gonococcic infection of any sort; the patient was a virgin and had no history of exposure. There was no gonococcic infection or history of such in her immediate family.

Bacteriologic Study.—Direct smears from the spinal fluid showed gram-negative cocci of typical neisserian morphology both inside and outside of the leukocytes. Cultures were made on rabbit's blood agar plates and in semisolid hormone agar. Growth appeared after forty-eight hours. In the semisolid agar a very delicate pellicle formed and on the blood agar a fine delicate growth of small translucent, discrete colonies occurred, quite characteristic of the gonococcus in appearance. This strain fermented dextrose readily but not maltose or any other sugar tested. It was agglutinated in a dilution of 1:200 in both polyvalent antimeningococcus serum and antigenococcus serum, but not by any of the type antimeningococcus serums. The result of the Thomson alkali solubility test

described by Pelouze⁴ was typical of the gonococcus. The culture and a sample of the patient's serum were sent to Dr. Carpenter at Rochester, N. Y. He found a complement fixation test with the serum for gonococcic infection to be 3 plus and the culture itself to be agglutinated in a dilution of 1:1,280 of antigenococcus serum and only 1:80 in the antimeningococcus serum that he had. There seems every justification for considering the micro-organism in question to be a gonococcus.

Bacteriologic Studies of Other Strains.—During the past two years ten of the cultures that have been sent to the senior author to be typed as meningococci have apparently been gonococci. Five of these were taken from spinal fluid of patients with meningitis, and five were taken from blood. With all ten strains colony formation and type of growth on blood agar were typical, dextrose alone was fermented, and all were agglutinated well by both antimeningococcus and antigenococcus serums, though to varying degrees. Most strains were completely dissolved in the alkali solubility test, whereas others were no more soluble than the meningococci used as controls.

The Source, Fermentation and Serologic Reaction and Alkali Solubility of Fourteen Strains of Gonococci*

* In the columns giving the serologic reactions, 4 indicates complete agglutination, 0 no agglutination, 1, 2 and 3 degrees of agglutination.

† These patients had a definite history of previous gonococcal infection of the genital tract

The most interesting feature was the reaction of these strains with meningococcus typing serums. Three of the five strains from the spinal fluid were agglutinated well by type II serum, though there was some degree of "crossing" with group I-III. Three of the five strains from the blood were also well agglutinated by type II serum, and the other two were agglutinated equally well by types I and II serums.

The question naturally arose How can one be sure that these are gonococci? What is a gonococcus, and what criteria may safely be used for its identification?

Known gonococci for comparative study were sent to us by Dr. Carpenter—two strains from the eye and one strain from the urethra. We obtained another from an arthritic joint. These and our ten blood and spinal fluid strains were studied with regard to type of growth, colony form, fermentation, serologic reaction and alkali solubility. These cultures were found to be indistinguishable from one another. Delicate growth on blood agar and small, translucent convex colonies were alike in all and were distinctly different from the more luxuriant growth of the meningococcus. Dextrose was readily fermented by all, but no other sugar was. All were often agglutinated by polyvalent antimeningococcus serum as well as by antigenococcus serum. Nearly all were agglutinated more strongly by type II antimeningococcus serum than by the other type serums, though there was considerable cross agglutination with some. The strain from the patient whose case

4. Pelouze, P. S.: *Gonorrhea in the Male and Female*, Philadelphia, W. B. Saunders Company, 1931.

is reported here and one strain from the eye in another case were the only two that were not agglutinated by type serums.

In the alkali-solubility test of Thomson described by Pelouze⁴ the gonococcus is usually instantly and completely dissolved, leaving a completely clear solution. Meningococci are partially dissolved but the stroma remains, leaving an opalescent fluid. Micro-organisms such as streptococci and staphylococci are untouched in the dilution of alkali used. The strains that we studied did not behave identically in this test. Five of the thirteen strains were completely and instantly dissolved, a clear, yellowish solution being left. These included two from the spinal fluid, two from the blood and one from the urethra. The eight remaining strains dissolved partially, leaving an opalescent fluid and some stroma, the reactions more nearly approaching those of the meningococci included in the test for comparative purposes.

The accompanying table summarizes the source of these strains, the characteristic fermentations, the serologic reactions and the alkali solubility.

COMMENT

Of 500 cultures sent to us during the last two years to be typed as meningococci, ten (or 2 per cent) have been found to be gonococci; one half of these, or 1 per cent, have been from spinal fluid and the other 1 per cent from blood. A complete detail of the history was not available in some of these cases, but it is definitely known that in five cases (2, 3, 6, 8 and 11) the meningeal or blood stream infection followed gonococcal infection of the genital tract. It is usually assumed that meningitis due to the gonococcus is secondary to gonococcal infection elsewhere. But in two of four patients who were observed by us, there was neither evidence nor history of other gonococcal manifestation obtainable. Both of these patients were young women—one the case described in this paper (case 1) and the other a nurse who had what seemed to be a primary gonococcal septicemia without meningeal involvement (case 7).

How can one be sure that the micro-organism in question is the gonococcus? What tests can be applied that definitely differentiate the gonococcus from the meningococcus?

Certain it is that our ten strains which appeared to be gonococci were indistinguishable in any way from those strains which had been isolated and identified as gonococci by workers who were experienced with that group of bacteria and that they differed in several respects from the many strains of meningococci which have been studied by us. How constant and how dependable are these differences? Cultural features and the type of colony were the most fundamental and typical differences that we have found. The persistently delicate growth and very small translucent colonies of the gonococcus have never been encountered by us with meningococci. The meningococcus is much more luxuriant and the colonies are larger.

Next in importance are the fermentation reactions. It has been well known for a long time that gonococci will ferment dextrose but no other sugars, and those which we have studied have followed this rule without exception. Among the approximately 1,000 strains of meningococci that have passed through our hands during the last ten years only four have seemed to ferment dextrose only, as does the gonococcus. It is possible that these may ultimately ferment maltose also, as other meningococcus strains have been inactive in this respect at first. At the time when a diagnosis is being made this failure of some strains of meningococci to cause characteristic fermentation may occasionally be confusing. Nevertheless, nearly all workers in this

field are agreed that the fermentation reactions are one of the most reliable aids in the identification of the gonococcus.

We have found the alkali solubility test of Thomson to be of definite value, though it is not an absolute criterion. Complete and rapid solution of the culture suspension has invariably indicated a gonococcus, though not all gonococci have given this complete reaction, as shown in the table.

Serologic methods of differentiation have not been satisfactory. Complete fixation with a patient's serum is indicative of infection with some member of the genus *Neisseria* and it is not species specific. Gonococci are well agglutinated by polyvalent antimeningococcus serum and usually by type serums. There is apparently an especially close relationship between gonococci and type II meningococci. This is especially interesting when the epidemiology of these infections is considered. During the last twenty years epidemics and small explosive outbreaks of meningococcal meningitis have been due chiefly to strains of the I-III group, whereas the cases due to type II have been sporadic. There has been a tendency for such cases to be milder and less responsive to treatment with antimeningococcus serum.⁵

CONCLUSIONS

It seems likely that gonococcal meningitis is much more common than it is usually supposed to be. Hospital laboratories are usually much too busy to carry the identification of the causative micro-organism to completion, and a gram-negative coccus of typical morphology which occurs intracellularly and extracellularly in the spinal fluid, and which is agglutinated by antimeningococcus serum, is usually assumed to be a meningococcus. Even when the study is carried further, definite criteria for the identification of the gonococcus are not well established and its identification is not easy. An absolute criterion is lacking. Nevertheless, a careful study of cultures with consideration of all of their characteristics—type of growth, colony form, fermentation reactions, alkali solubility and serologic reactions—will make an experienced worker feel quite sure of the identity of the strain in question.

Although gonococcal meningitis is usually secondary to gonococcal infection elsewhere, the case reported in this paper suggests that the gonococcus must be considered a potential cause of a primary meningitis without other gonococcal involvement.

National Institute of Health.

5. Since this paper was written we have observed three additional cases of gonococcal meningitis and have studied the cultures obtained from them. In all three of these cases there were histories of previous gonorrheal infection. The following additional reports of cases of gonococcal meningitis have appeared in the literature:
Marvin, H. P., and Wilkinson, W. E.: *Gonococcal Meningitis: Results of Treatment with Sulfanilamide*, J. A. M. A. **110**: 800-802 (March 12, 1938).

That Strange Genius, Paracelsus.—Here and there men of science could be found groping through the thick fogs of ignorance, fear and superstition that enshrouded in mystery the phenomena of mental disease. Among the earliest of these was that strange genius, Paracelsus, dabbler in alchemy and astrology, an eccentric and braggart—and a great physician. Before meeting death in a tavern brawl in 1541, Paracelsus had rendered medical science a great service by repudiating galenism and the humoral pathology that had dominated medical practice for more than fifteen centuries. He ridiculed the notion of demoniacal possession.—Deutsch, Albert: *The Mentally Ill in America*, New York, Doubleday, Doran & Co., Inc., 1937, p. 21.

THE "COLD PUNCH" TYPE OF
PROSTATIC RESECTION

SIX YEARS OF PROGRESS

JOHN L. EMMETT, M.D.

ROCHESTER, MINN.

The principle of removing obstructing prostatic tissue through the urethra by means of a cold, cutting, tubular knife sliding in an outer fenestrated sheath was given its first serious trial in the Young punch.¹ The principle was further carried on in the Braasch "median bar excisor."² For obvious reasons neither instrument was adapted for the removal of substantial amounts of prostatic tissue and neither provided adequate means for hemostasis. The first "cold cutting" resectoscope that overcame these difficulties was the Braasch-Bumpus resectoscope.³

Although a few prostatic resections were done each year for several years previous to 1930, it was not until 1931 that they were done in enough volume at the Mayo Clinic to assume importance. The subsequent

in performing transurethral resection;⁴ important among these is the teaching regarding preoperative preparation. For instance, whereas formerly drainage by catheter for ten days was insisted on almost as a routine in cases in which suprapubic drainage was not immediately established, today drainage by catheter is employed only if nitrogen is retained in the blood. Drainage by catheter is terminated just as quickly as the concentration of blood urea can be reduced to 50 mg. per hundred cubic centimeters or less. For the same reason the incidence of preliminary suprapubic drainage has steadily declined, as is shown by the fact that in 1933 preliminary suprapubic cystostomy was performed on twenty-eight of the 451 patients subjected to transurethral resection, whereas in 1936 it was performed on only eleven of the 749 patients who were subjected to this type of resection.

Another striking observation over this period of six years is the increase in the number of patients of advanced age who were subjected to operation. This can be explained by the fact that there are accepted for transurethral resection patients who present a poorer risk than that presented by patients who formerly were

rapid rise of this type of surgery has been phenomenal, as is demonstrated by the fact that at the Mayo Clinic in 1931 ninety-nine resections were done on eighty-seven patients, while, in 1936, 835 resections were performed on 749 patients. In 1931 transurethral resection accounted for 40 per cent of the year's prostatic surgery, while in 1936 it accounted for 99.6 per cent of the year's prostatic surgery. For the six years from 1925 to 1930 inclusive, an average of 255 patients a year were subjected to prostatectomy; in 1936, 749 patients were subjected to transurethral resection. This suggests that the fear of prostatic surgical operations is decreasing and patients are seeking earlier relief.

During the period of six years 1931 to 1936 inclusive transurethral surgery had been rapidly improving, and each year the operation was being performed better than in the previous year, owing to improvement in technic and in instruments and to better knowledge of the surgical principles involved. Several axioms of suprapubic and perineal prostatectomy have had to be unlearned

accepted for prostatectomy and that men whose physicians formerly would have advised against their seeking surgical relief because of their advanced age are being referred for operation. Evidence of the increasing number of older patients can be seen in table 1. It will be seen that of patients subjected to prostatectomy 20.5 per cent were 70 years of age or older and only 1.2 per cent were more than 80. Of the patients subjected to transurethral resection, 31.7 per cent were 70 years of age or more, whereas 3.9 per cent were more than 80.

The average period of postoperative confinement in the hospital remains almost constant, year after year, at about eight days. The mortality rate, although it fluctuates from year to year, continues to be low, as is shown in table 2.

Probably the most important recent advance in transurethral prostatic resection is that larger amounts of prostatic tissue than formerly are being removed. When transurethral surgery began, it was thought necessary to cut only a "channel" or "gutter" through the prostatic urethra. This channel soon was found to be inadequate. Later it was felt that, if all the obstructing tissue of the median lobe and the intravesical portions of the lateral lobes were removed, the remaining

intra-urethral portions of the lateral lobes would cause no difficulty for the patient. The results with this type of resection were entirely unsatisfactory and the patient continued to suffer with residual urine, dysuria and urinary infection. It soon became evident that all the intravesical tissue, and as much of the intra-urethral tissue as possible, should be removed. Symptoms of

scope⁶ (fig. 1). Embodying the fundamentals of the Braasch-Bumpus resectoscope, it allows also cutting under visual control. Providing a self-contained unit, with the water inlet on the knife and a large outlet valve, it is possible to resect tissue rapidly and accurately. Instead of several steps being required for removal of each piece of tissue, several pieces can be cut rapidly and allowed to fall into the bladder, subsequently to be washed out through the outlet valve or to be aspirated with the evacuating syringe. With the Bugbee electrode always in place, individual bleeding points can be fulgurated instantly as they appear, reducing the loss of blood to a minimum.

Since Sept. 1, 1936, except in a few instances, the Thompson instrument has been used exclusively at the Mayo Clinic with excellent results, and we have found it extremely satisfactory for several reasons. From the surgeon's standpoint it is much easier to use. For instance, if tissue is in an extremely awkward position to be engaged when the scope has once been maneuvered into position, this portion of the prostate gland can be rapidly resected instead of its being necessary repeatedly to maneuver the scope into the difficult position required to engage each piece of tissue. With the increased length of the scope, tissue is more easily engaged, for greater leverage is available (the perineum acting as the fulcrum). This greater leverage reduces the manual strength required, so that the surgeon's arm and fingers do not tire so easily. Because the cutting is done under visual control and the length of the bite can be varied by opening the fenestra to any desired length, it is possible to remove tissue at the apex of

TABLE 2.—Mortality Rate of Transurethral Prostatic Resection for the Six Years from 1931 to 1936 Inclusive

obstruction recurring in from one to two years were found to be due to the removal of an insufficient amount of tissue at the first operation.

When the procedure is transurethral prostatic resection, we have always felt at the clinic that the patient should not be subjected to a longer period of operation than one hour. If the period of operation is extended, the operative risk becomes unduly high. It is much preferable, when a large prostate gland is encountered, to subject the patient to a second resection from five to ten days after the first than to prolong the operation. With the Braasch-Bumpus resectoscope, because of the

number of technical steps required to remove each bite of tissue, from 30 to 45 Gm. of tissue is about the maximal amount that can usually be removed in from fifty to sixty minutes by an experienced surgeon. Often, in operating on a moderately large prostate gland, this gives a good functional result even though considerable tissue remains. With such a satisfactory functional result the surgeon hardly feels justified in advising, and the patient is loath to accept, a second resection to remove the remaining tissue. A small percentage of the patients will return in two or three years either with further symptoms of obstruction or with aggravating intermittent hematuria attributable to remaining adenomatous tissue that requires further resection. It becomes more and more apparent that to give the most satisfactory results transurethral resection must approach total prostatectomy. "Transurethral prostatectomy" must eventually replace "transurethral prostatic resection."

An important step in this direction has been the introduction of the Thompson "cold cutting" resecto-

scope with much less danger of injuring the external sphincter than would be entailed otherwise. Because of the rapidity with which the instrument can be operated, from 55 to 80 Gm. or more of tissue can be removed easily in a period of from forty-five to sixty minutes. As a result, almost complete prostatectomy is performed in a large percentage of cases.

Also important among the factors promoting more complete removal of tissue is the more liberal use of digital counterpressure in the rectum exerted by an assistant. Especially in the case of a pocketed urethra, this maneuver helps greatly in engaging tissue. If too strenuous attempts are made to engage tissue in such a urethra without counterpressure, the trigon and external sphincter may be considerably traumatized.

The results from the more nearly complete removal of prostatic tissue are gratifying. Delayed postoperative bleeding (which usually arises several months after

5. Thompson, G. J.: A New Direct Vision Resectoscope, Urol. & Cutan. Rev. 30: 545-546 (Aug.) 1935.

operation in remaining remnants of adenomatous tissue) has become extremely uncommon. Convalescence is much smoother and the urinary infection is eradicated with remarkable rapidity; it is not uncommon to see patients from five to seven weeks after resection of a large prostate gland whose urine is crystal clear. Post-operative frequency and nocturia have been much reduced. It recently has become apparent that the

Fig. 1.—Thompson resectoscope.

judicious administration of sulfanilamide for a short period, about six weeks after resection, is exceedingly helpful in clearing the urine. When the cold cutting resectoscope is used, if resection has been completely done, the prostatic urethra is usually clean, well healed and free from bits of sloughing tissue in from four to six weeks following operation. After this period has elapsed, if the urine remains hazy, administration of sulfanilamide, 10 grains (0.65 Gm.) four times a day for from six to nine days, in the great majority of cases will cause the urine to become clear almost immediately. Sulfanilamide given preoperatively or immediately after operation, however, seems to be of little or no value. This statement has been carefully verified here by Gaudin, Zide and Thompson⁶ in a large series of cases with controls.

For the purpose of illustrating the gradual tendency to remove larger amounts of prostatic tissue in transurethral resection, I have compared the work done in September 1937 with that done in each preceding September to and including 1931. There are several reasons for choosing September: It is the most recent month tabulated at the writing of this paper; it marks the completion of one year's almost exclusive use of the Thompson resectoscope, which has allowed time to acquire proficiency in its use. Also, our statistics at the clinic show that in the fall of the year prostate glands seem to be somewhat larger than at other seasons. This is probably explained by the fact that patients who have only large intra-urethral lateral lobes tend to suffer with acute episodes of obstruction at the onset of cold weather. A comparison of the work done in individual months will, I believe, better portray the status of transurethral resection at each definite stage of its development. As will subsequently be brought out in this paper, there is no reason to feel that prostate glands encountered vary in size from year to year.

A comparison of the work done in each September, from 1931 to 1937 inclusive, is interesting. One must remember, in studying the data presented subsequently, that the weight of tissue given is per resection and for that reason does not always indicate the total amount removed from a patient. For instance, the 100 resec-

tions done in September 1937 were performed on ninety-seven patients, signifying that three resections were secondary operations. Table 3 shows the marked increase in the amount of tissue removed per resection from year to year. The gradual increase was, of course, due to the improvement in technic as a result of increased experience. However, it will be noticed that there was a striking increase in the weight of tissue removed in September 1936 and September 1937. For instance, in September 1936 more than 30 Gm. of tissue was removed in 26 per cent of the resections, while in September 1937 more than 30 Gm. was removed in 33 per cent of the resections and more than 60 Gm. was removed in 5 per cent. The average weight of tissue removed per resection in September 1937 was 25.3 Gm.

In table 4 is given the approximate time that was required for resection in various years. It will be seen that in each succeeding year there was a gradual reduction in the operating time per gram of tissue removed. This no doubt was due to the gradual refinement of technic resulting from greater experience. The outstanding reduction in operating time, however, is seen to have been in the September 1937 group of cases. In table 5 this is demonstrated more clearly, as it is seen that in this month 85 per cent of the resections were completed in forty-five minutes or less, in spite of the fact that more than 40 Gm. of tissue was removed in 21 per cent of the cases. This sudden reduction in operating time is largely due to the rapidity with which the Thompson resectoscope can be operated.

The question is often raised as to what proportion of the prostate gland is removed at resection. For the first nine months of 1937 the average weight of tissue removed per patient was 23.6 Gm. From 1912 to 1931 inclusive, prostatectomy (either suprapubic or perineal) was performed at the Mayo Clinic in 3,629 cases. Of these cases we have the record of the weight of the prostatic tissue removed in 3,205, and in this group the average weight of tissue removed was 44.1 Gm. The highest average for any one year of this period was 51.3 Gm.; the lowest, 41.2 Gm. (fig. 2). This comparison, however, is not entirely fair to transurethral resection, for the average weight of tissue in

Fig. 2.—Average weight of tissue removed at prostatectomy from 1912 to 1931.

the group of cases in which transurethral resection was performed is considerably lowered by the many cases of median bar and contracture of the vesical neck in which, formerly, the risk of prostatectomy would not have been accepted. We have included every such case in tabulating the results of transurethral resection. If these cases were eliminated the average weight of tissue removed at resection would be materially increased. From these data it must be concluded that considerably more of the gland is being removed at transurethral resection than is generally supposed. As regards the incidence of "large prostates," it is of interest to note

6. Gaudin, H. J.; Zide, H. A., and Thompson, G. J.: Data Concerning Administration of Sulfanilamide Following Transurethral Prostatectomy, unpublished data.

that, of 3,205 prostate glands removed suprapubically or perineally at the Mayo Clinic between 1912 and 1931, only 7.3 per cent weighed more than 100 Gm.

The majority of distressing postoperative complications and accidents discussed in the urologic literature in relation to transurethral resection are rapidly disappearing as the general technic throughout the country improves with increased experience. There is one

TABLE 4.—Comparison of Length of Operative Period

complication, however, that, although it is of rather uncommon occurrence, still presents a problem in transurethral surgery. This is postoperative urethral stricture. It is rather difficult to estimate the incidence of postoperative stricture. Certainly there are cases in which a stricture of large caliber develops but never gives enough trouble to make the patient seek urologic advice. I would estimate that the possible incidence of postoperative urethral stricture at the Mayo Clinic has been from 1 to 1.5 per cent. Most of these strictures are slight and respond to one or two dilations. The majority are found in the anterior urethra, in the region of the penoscrotal angle, and occasionally they may be extremely difficult to dilate. In these cases internal urethrotomy is performed with the Riba⁷ high frequency urethrotome and results are excellent. This procedure carries little if any risk, and in many cases the results seem to be permanent.

It is generally agreed that the cause of these strictures is the passing through the urethra of too large an instrument. If the resectoscope is tight in the urethra the chances of formation of stricture are increased. If too large an instrument is forced through the urethra and the mucosa is torn, the chance of a stricture forming is still greater. For that reason the Braasch-Bumpus instrument is manufactured in two sizes, 24 and 28 F., and the Thompson resectoscope in sizes 27 and 30 F. The one rule that we attempt to follow is never to pass an instrument through the urethra if it is too tight. Nevertheless, in occasional cases strictures will form even when the urethra has been of adequate caliber for the resectoscope. In such cases the stricture is nearly always at the penoscrotal angle and no doubt arises from the trauma induced by motion of the resectoscope back and forth in engaging tissue. It is believed that the incidence of this type of stricture may be somewhat reduced with the new resectoscope, since fewer motions are involved in its use.

Probably the best solution yet devised to prevent postoperative stricture is that of "perineal prostatic resection," as recently described by Thompson⁸ and Cabot.⁹ If this procedure is used in all cases in which

the urethra is too narrow to allow the resectoscope to pass freely, the incidence of postoperative stricture should be reduced to an almost negligible figure. This procedure makes use of the fact that the bulbous urethra is nearly always of large caliber. Over the tip of a sound that has been passed into the bulbous urethra external urethrotomy is performed and the resectoscope is introduced into the bladder through this incision. Following the resection the indwelling catheter is inserted through the penile urethra as usual, and the perineal wound is allowed to close without stitches. The wound is usually healed sufficiently by the fourth day so that leakage does not occur when the patient voids after removal of the catheter.

The results obtained with transurethral surgery of the prostate gland in this period of more than six years have been very satisfactory, and it is felt that it is now the procedure of choice in practically all cases of obstructing prostate glands. With increased experience and improved instruments one might safely predict that transurethral resection will become known in the literature of the future as transurethral prostatectomy.

COMMENT AND SUMMARY

Transurethral resection has dispelled much of the fear of prostatic surgical procedures among laymen. Because of this, a much larger number of patients are seeking surgical relief of prostatic obstruction than in the days when prostatectomy was the sole method employed. A part of this increase is also due to the large proportion of older men who formerly were regarded as offering too poor surgical risks.

The incidence of preliminary suprapubic drainage before resection is rapidly declining and drainage by catheter is employed only in cases in which nitrogen is being retained. The most important advance in resection has been the removal of larger amounts of tissue and reduction in operating time, owing to increased technical experience and improved instru-

TABLE 5.—Per Cent of Resections Completed Within a Forty-Five Minute Operative Period Compared with Weight of Tissue Removed

1937	85	33.0	21.0	10.0	5.0

ments. Because of this removal of larger amounts of tissue, convalescence is smoother and results are more satisfactory than before. The judicious use of sulfanilamide several weeks after resection is of distinct value. Postoperative urethral stricture can be reduced to an almost negligible minimum if "perineal prostatic resection" is employed in cases in which the urethra is too tight to admit the resectoscope readily. The statistics comparing the progress of six years suggest that transurethral resection is eventually to become transurethral prostatectomy.

THE TREATMENT OF ALCOHOLIC
PSYCHOSES WITH BENZED-
RINE SULFATE

PRELIMINARY REPORT

EDWARD C. REIFENSTEIN JR., M.D.
AND

EUGENE DAVIDOFF, M.D.

SYRACUSE, N. Y.

Alcohol is recognized to have a depressing effect on the central nervous system.¹ It therefore seemed rational to us² to attempt treatment of psychoses due to intoxication from alcohol with benzedrine sulfate (beta-phenylisopropylamine sulfate), which has been established to have a stimulating effect on the central nervous system.³ Because of the nature of the results it appeared desirable to present this preliminary report.

A series of patients admitted to the Syracuse Psychopathic Hospital in psychotic states brought on by alcohol were subjected to careful physical and mental observation and then given from 10 to 30 mg. of benzedrine sulfate by mouth daily. In a few instances from 10 to 30 mg. of the drug was administered intravenously.⁴ In all cases the diagnosis was made according to the classification adopted by the American Psychiatric Association.

In an estimation of the influence of the drug in these cases consideration was given to (a) the opinion of staff members who were unaware of the medication employed in a given case, (b) the response as compared with control cases and (c) the rapidity of dissipation of the psychotic state, including confusion, with acceleration of improvement in mood, speech and coordinate motor activity, accessibility and general efficiency.

In general it may be said that mild states of depression following drinking debauches respond in an exceedingly striking manner to benzedrine sulfate. Doses of from 10 to 20 mg. of the drug given by mouth in the morning will often produce marked improvement within twenty-four hours. Several persons with alcoholic stupor were aroused within thirty minutes after the injection of from 10 to 30 mg. of benzedrine sulfate intravenously. As is to be expected, those with pathologic intoxication reacted very favorably to the drug. In cases of delirium tremens and of early acute hallucinosis the response was also satisfactory. In cases of chronic hallucinosis and of Korsakoff's psychosis the results were not as gratifying. Benzedrine sulfate appeared to be of most value in the treatment of alcoholic psychosis of recent onset in which organic defects of the sensorium, deterioration or personality alterations had not developed.

Some of the results are indicated in the accompanying table. A definitely and at times markedly accel-

erated rate of improvement was obtained in 93 per cent of twenty-eight patients, including fifteen patients with pathologic intoxication, five with delirium tremens, four with acute hallucinosis and four with Korsakoff's syndrome. One patient with pathologic intoxication from methyl alcohol responded very satisfactorily. In cases of delirium tremens the results with benzedrine sulfate were at least as effective as those obtained with drainage of the spinal fluid. Except for two patients with Korsakoff's psychosis complicated by arteriosclerosis, none thus far treated with benzedrine sulfate have required commitment to a hospital for chronic mental patients. We have observed⁵ that the drug at times may be of value in differentiating the states of depression due to alcohol alone, which are usually

rapidly dissipated by the drug, from the states of depression superimposed on and masking depressions of psychogenic origin, which do not respond as rapidly to the drug.

In states of intoxication with alcohol in which no psychosis was demonstrable, benzedrine sulfate usually produced an even more satisfactory response than in states of intoxication in which a psychosis existed. The headache, fatigue, languor and mental retardation which are characteristic of a "hang-over" usually disappeared within an hour or so after a morning dose of from 5 to 10 mg. A similar response in several patients was mentioned by Wilbur, MacLean and Allen.⁵ We suggest that benzedrine sulfate may produce these beneficial responses in alcoholic states through its action of stimulating the central and the sympathetic

nervous system and also directly by neutralizing or antagonizing the alcohol itself.

A number of persons have compared the sensations produced by benzedrine sulfate with those of a mild state of alcoholic intoxication; one characterized his experience as "a cheap jag." Those who had a liking for spirituous liquors particularly relished the drug. Because of these pleasurable sensations many persons request the drug or procure it for themselves at pharmacies. We are convinced that, in certain persons at least, benzedrine sulfate is habit forming. We have observed such tendencies in persons addicted to alcohol, morphine and other drugs; in neurotic persons who crave medication, and in people who work under excessive strain, such as actors, students, nurses and physicians.

That alcoholism is often a manifestation of an underlying psychoneurotic personality is well recognized. Benzedrine sulfate may prove to be of value in overcoming alcoholic habituation; however, it is open to question whether this drug should be administered to persons who have demonstrated a tendency to addiction by their chronic alcoholic habits.

Because of this danger of addiction, because of the relatively frequent and unpredictable occurrence of untoward effects (as we have previously mentioned²) and because of the occasional appearance of serious toxic reactions,⁶ we believe that the use of benzedrine sulfate in states of alcoholism with or without psychosis can rarely be justified outside of institutions. That successful treatment of chronic alcoholism itself requires hospitalization in an institution set aside for this purpose is becoming increasingly apparent, and this is evidenced by the proposed erection of such an institution by the state of New York. Only by thus restricting the use of benzedrine sulfate to inpatients can physicians be assured of adequate supervision, which will minimize the dangers of unfavorable events and prevent the abuse of this useful drug.

SUMMARY

1. In twenty-eight patients with psychosis due to intoxication from alcohol, benzedrine sulfate produced a definite and at times a marked acceleration of improvement in 93 per cent. The drug appeared to be of most value in the cases of recent onset but exercised a favorable influence on alcoholic depressions in general.

2. In states of intoxication brought on by alcohol in which no psychosis was demonstrable an even more satisfactory response to benzedrine sulfate was obtained. The depressive after-effects of alcoholism were usually rapidly dissipated.

3. The use of benzedrine sulfate in states of alcoholism with or without psychosis should be limited to institutionalized patients, in whom the dangers of habit formation with benzedrine sulfate itself and of harm from unpredictable untoward effects or serious toxic reactions can be adequately safeguarded. Under these conditions the drug may prove to be of value in overcoming chronic alcoholic habituation.

FATALITIES FOLLOWING INJECTION TREATMENT OF HERNIA

CLARENCE J. BERNE, M.D.

LOS ANGELES

In estimating the value of the injection treatment of hernia, a significant consideration is its adaptability to use by those who treat relatively few cases, and especially those who have not been accustomed to applying the surgical treatment for hernia. Because many such individuals are now treating hernia by the injection method, and because its extreme safety has been so strongly stressed by many writers, it seems justifiable to submit evidence to the contrary, in an effort to emphasize certain inherent dangers in the method. The ultimate status of the injection treatment will depend largely on the percentage of cures indicated by unbiased critical follow-up studies of not less than three year periods. At present such conclusions cannot be drawn.¹ In the meantime considerable evidence should accrue regarding the more acute complications of the treatment. This report is a consideration of two deaths due to the injection of inguinal hernia, in which the complication arose from too deep insertion of the needle, producing an intraperitoneal injection. Two previous cases are reported in the literature.² The factors surrounding cases of this type are such as to lessen the chances of their being reported. This suggests a higher incidence of the complication than the literature would indicate.

The occurrence of intraperitoneal injection must be assumed to vary considerably, being lowest in the hands of those skilled in the method and increasing in frequency in the hands of those with more limited experience. Some writers emphasize the importance of deep injections in obtaining good results.³ Those following this technic rather than trying to inject just below the external oblique aponeurosis will certainly have a higher incidence of intraperitoneal injections. In their own series Harris and White³ report this complication eight times in 3,000 injections. This may be taken to represent an incidence of approximately one intraperitoneal injection in every twenty cases treated for unilateral hernia and may be accepted as a minimum incidence of the complication.

Most writers on the technic of injection treatment consider the problem of intraperitoneal injection at some length, as it obviously is the most significant danger in the method. It is emphasized that all injections be given slowly, so that a minimum amount of sclerosing fluid will have been given in case that characteristic diffuse hypogastric pain occurs. There are admittedly no criteria which indicate before the injection is started that the needle has entered the peritoneal cavity. It is emphasized in the literature that this immediate reaction should not be considered an indication for laparotomy because the reaction passes quickly and there are no sequelae. In contrast to these conceptions, it is my opinion that the fibrinous chemical peritonitis resulting from the presence of the fluid can produce adhesions as a part of the healing process and

condition the development of intestinal obstruction. Such cases are being recognized. In addition to this danger it is undeniable that the needle can be inserted into the bowel wall and even into its lumen. Injection of the bowel wall, particularly if complicated by infection, may produce sloughing, perforation and peritonitis. The following cases represent complications of this type. Both were admitted to the Los Angeles General Hospital in a condition requiring immediate attention, their previous treatment having been given elsewhere. The injection had been made in one instance by an irregular practitioner, in the other by a regular physician specializing in the injection treatment.

REPORT OF CASES

CASE 1.—J. S., a man aged 57, a laborer, had acquired bilateral inguinal hernia approximately three years before. Injection treatment had recently been started, four injections having been made on the left and two on the right side. Three days preceding admission a third injection of quinine and urea hydrochloride was given on the right side, followed by severe pain in the right lower quadrant. The severe pain lasted two hours and gradually decreased until it was but slight after twelve hours. The following morning (eighteen hours later) vomiting occurred, persisted with increasing frequency to the time of admission and was associated with obstipation.

Examination revealed that the patient was toxic and dehydrated, with a temperature of 98.6 F., pulse rate 124 and respiratory rate 24. The arterial blood pressure measured 116 mm. of mercury systolic and 88 diastolic. The abdomen was distended, diffusely rigid and tender, and only an occasional peristaltic sound was heard. No significant abnormalities were present in the urine. The white blood cells numbered 7,600, with 93 per cent of polymorphonuclear leukocytes.

Laparotomy was done soon after admission. A 2 cm. perforation of the ileum was found on its antimesenteric border, about 75 cm. from the ileocecal valve. This was surrounded by a large amount of plastic exudate, partially walling off the bowel content which had been passed out through the opening. A large part of this bowel content was a green vegetable. Two rows of Lambert sutures were placed to close the perforation transversely and the peritoneal cavity was drained. Death occurred eighteen hours later. Autopsy revealed an acute generalized peritonitis.

CASE 2.—M.F.D., a man aged 47, a laborer, entered the hospital complaining of abdominal pain. Ten days before, following injection given for bilateral inguinal hernia, he had abdominal pain and diarrhea. He was treated for enteritis and was able to resume work. Five days before admission to the hospital he had severe left lower quadrant pain, associated with collapse. Many details of the history could not be learned.

The patient was very ill. The temperature was 99.4 F., pulse rate 108, respiratory rate 28. The arterial blood pressure measured 150 mm. of mercury systolic and 90 diastolic. There was marked abdominal distention, with tenderness graded three plus in both lower quadrants, and proportionate rigidity. Peristalsis was present in the upper part of the abdomen. By rectum a boggy tender mass was palpated at the upper limit of the finger's reach. A "scout" film of the abdomen showed multiple coils of intestine, both small and large, distended with gas. No pathologic changes were found in the urine. Blood examination was not made.

Laparotomy was carried out soon after the patient's admission. The lower quadrants presented a purulent exudate with a foul odor, and on the left there was considerable clotted blood. The sigmoid seemed torn from its lateral attachment and presented a 2 cm. perforation. For about 7 cm. in each direction the sigmoid looked gangrenous. The discolored area was resected, the distal segment closed and dropped, and the proximal end brought out as a single barreled colostomy. The patient died soon after the laparotomy.

Culture of the peritoneal exudate grew *Escherichia coli* and *Streptococcus viridans*. Microscopic study of the margin of

the perforation showed young granulation tissue, hemorrhage and an acute inflammatory exudate. Autopsy disclosed approximately 400 cc. of bloody fluid in the upper part of the abdomen and a fibrinopurulent exudate throughout the lower part of the abdomen.

SUMMARY

In the two cases reported, death was due to an injection made in the course of treatment for inguinal hernia. In the first case the acute process progressed from the time of injection, and in the second case after an initial syndrome suggesting severe irritation of the bowel wall a quiescent period occurred, with a sudden acute progressive episode five days later, probably indicating the time of perforation. These cases constitute an indictment against the teaching that intraperitoneal injection is a harmless accident and establish that laparotomy may be necessary at any time, as an emergency procedure, on the appearance of symptoms and signs indicating a significant variation from the usual clinical course following intraperitoneal injection.

PRECOCIOUS SEXUAL DEVELOPMENT
FROM AN ANTERIOR PITUITARY-
LIKE PRINCIPLE

WILLARD O. THOMPSON, M.D.

AND

NORRIS J. HECKEL, M.D.

CHICAGO

Rapidly accumulating evidence clearly shows that the anterior pituitary-like principle from the urine of pregnant women exerts a profound influence on the growth and function of the male genitalia. It may produce an increase in the size of the penis, scrotum and prostate in both man¹ and animals² before the age of puberty. The consensus is that in the testis it influences primarily the interstitial cells,³ although there is some evidence

The arterial blood pressure measured 116 mm. of mercury systolic and 88 diastolic. The abdomen was distended, diffusely rigid and tender, and only an occasional peristaltic sound was heard. No significant abnormalities were present in the urine. The white blood cells numbered 7,600, with 93 per cent of polymorphonuclear leukocytes.

Laparotomy was done soon after admission. A 2 cm. perforation of the ileum was found on its antimesenteric border, about 75 cm. from the ileocecal valve. This was surrounded by a large amount of plastic exudate, partially walling off the bowel content which had been passed out through the opening. A large part of this bowel content was a green vegetable. Two rows of Lembert sutures were placed to close the perforation transversely and the peritoneal cavity was drained. Death occurred eighteen hours later. Autopsy revealed an acute generalized peritonitis.

CASE 2.—M.F.D., a man aged 47, a laborer, entered the hospital complaining of abdominal pain. Ten days before, following injection given for bilateral inguinal hernia, he had abdominal pain and diarrhea. He was treated for enteritis and was able to resume work. Five days before admission to the hospital he had severe left lower quadrant pain, associated with collapse. Many details of the history could not be learned.

The patient was very ill. The temperature was 99.4 F., pulse rate 108, respiratory rate 28. The arterial blood pressure measured 150 mm. of mercury systolic and 90 diastolic. There was marked abdominal distention, with tenderness graded three plus in both lower quadrants, and proportionate rigidity. Peristalsis was present in the upper part of the abdomen. By rectum a boggy tender mass was palpated at the upper limit of the finger's reach. A "scout" film of the abdomen showed multiple coils of intestine, both small and large, distended with gas. No pathologic changes were found in the urine. Blood examination was not made.

Laparotomy was carried out soon after the patient's admission. The lower quadrants presented a purulent exudate with a foul odor, and on the left there was considerable clotted blood. The sigmoid seemed torn from its lateral attachment and presented a 2 cm. perforation. For about 7 cm. in each direction the sigmoid looked gangrenous. The discolored area was resected, the distal segment closed and dropped, and the proximal end brought out as a single barreled colostomy. The patient died soon after the laparotomy.

Culture of the peritoneal exudate grew *Escherichia coli* and *Streptococcus viridans*. Microscopic study of the margin of

the perforation showed young granulation tissue, hemorrhage and an acute inflammatory exudate. Autopsy disclosed approximately 400 cc. of bloody fluid in the upper part of the abdomen and a fibrinopurulent exudate throughout the lower part of the abdomen.

SUMMARY

In the two cases reported, death was due to an injection made in the course of treatment for inguinal hernia. In the first case the acute process progressed from the time of injection, and in the second case after an initial syndrome suggesting severe irritation of the bowel wall a quiescent period occurred, with a sudden acute progressive episode five days later, probably indicating the time of perforation. These cases constitute an indictment against the teaching that intraperitoneal injection is a harmless accident and establish that laparotomy may be necessary at any time, as an emergency procedure, on the appearance of symptoms and signs indicating a significant variation from the usual clinical course following intraperitoneal injection.

PRECOCIOUS SEXUAL DEVELOPMENT FROM AN ANTERIOR PITUITARY- LIKE PRINCIPLE

WILLARD O. THOMPSON, M.D.

AND

NORRIS J. HECKEL, M.D.

CHICAGO

Rapidly accumulating evidence clearly shows that the anterior pituitary-like principle from the urine of pregnant women exerts a profound influence on the growth and function of the male genitalia. It may produce an increase in the size of the penis, scrotum and prostate in both man¹ and animals² before the age of puberty. The consensus is that in the testis it influences primarily the interstitial cells,³ although there is some evidence

that the seminiferous tubules may also be affected.⁴ Some increase in the size of the testes has been produced in rats⁵ and monkeys.⁶ In the course of treating patients for undescended testes we have been struck more by its influence on the growth of the genitalia than by its influence on the descent of the testis.⁷ It will be shown that this stimulation of genital growth may be so marked that changes simulating premature puberty are produced.

DATA

In the course of treating thirty-three patients for undescended testis with the anterior pituitary-like principle,⁸ genital growth was produced in eighteen, and in fourteen it was marked. In two of them, aged 7 and 9 years, a condition resembling premature puberty resulted. The penis became as large as that of an adult. There was an increase in the size of the scrotum and prostate, a growth of pubic hair, a marked increase in frequency of erections, a change in the pitch of the voice, and in one a growth of hair on the sides of the face. Similar changes were produced in a 4 year old boy out of a total of twelve patients with hypogenitalism, and less marked growth in eight others. The boy showing changes simulating premature puberty was of normal body contour but had an atrophic left testis. All boys showing genital growth became more masculine. It should be pointed out that in some of the patients with undescended testes and hypogenitalism who failed to show any growth the dose may have been inadequate, there being several examples in our series of failure of growth with a small dose and a well marked growth with a larger dose.

REPORT OF THREE CASES IN WHICH A SYNDROME SIMULATING PREMATURE PUBERTY DEVELOPED

CASE 1.—T. D., an Italian boy aged 6 years and 7 months came to the clinic July 16, 1936, because of failure of descent of the right testis. He was of normal body contour but slightly short for his age. In the erect posture the right testis was at the level of the external ring but could not be displaced downward. There was some question of a right inguinal hernia, which may have accounted for a painful swelling which had occurred occasionally since he was 2 months old. The penis measured 3.8 by 1.9 cm. and the left testis 2.2 by 1.2 cm. The prostate was not palpable. Treatment with follutein was begun August 7 and the dose rapidly increased to 200 rat units six times a week. September 11, after he had had a total of 5,370 units, his mother stated that the right testis had been

in the scrotum since two weeks after the treatment was started. However, on physical examination the right testis was felt just above the upper end of the scrotum with the patient in the upright position and could be pulled into the upper end of the scrotum. The penis and scrotum were larger, erections were more frequent and he had started to masturbate. September 24, after a total of 7,570 units, the right testis, associated with what appeared to be a hernia, was in the upper end of the scrotum and could be pulled to a lower level in the scrotum. The penis measured 5.1 by 2.7 cm. and the left testis 2.8 by 1.9 cm. There were several pubic hairs as much as 0.9 cm. long. The prostate was about 2 cm. in diameter. Erection continued to be frequent. October 30, after he had had a total of 13,170 units of follutein, both testes were in the scrotum but the right testis was attached to what was thought to be a peritoneal pouch. The penis measured 5.4 by 2.5 cm. and the left testis 2.5 by 1.4 cm. The prostate was about 3 cm. in diameter and was full. The pubic hairs were as much as 1.6 cm. long. The scrotum had enlarged. December 11, after he had had a total of 19,770 units, the right testis was in the upper end of the scrotum and estimated to be about 0.7 cm. in diameter. Extending for from 2.5 to 3.8 cm. below it was the fluctuant mass previously described. The penis measured 7 by 3 cm. and the left testis 2.5 by 1.4 cm. The pubic hair had grown so that it was as much as 4.4 cm. long. The prostate was enlarged, well defined and about 2.5 cm. in diameter.

Jan. 15, 1937, after he had had a total of 24,970 units of follutein, the right testis was still in the upper end of the scrotum with a sac extending below it. The penis measured 6.7 by 3.2 cm. and the left testis 2.9 by 1.6 cm. The prostate was 2.5 cm. in diameter. There was a marked increase in pubic hair, which was as much as 5.1 cm. long. February 26, after a total of 26,770 units, the right testis was in the upper end of the scrotum and surrounded by a sac which extended 2.5 cm. below it. This sac was not in the scrotum before treatment was started and with treatment had grown down to the lower end of the scrotum, which had also enlarged. The penis measured 6.4 by 3.8 cm. and the left testis 2.9 by 1.9 cm. The right testis was in about the same position. The prostate was about the same size as on the previous examination, and the pubic hairs were abundant and as much as 7 cm. long. It was stated that his voice began to show lowering of pitch about one month after the treatment was started. The hair on the sides of his face was long for his age, but we could not be sure whether it had grown during treatment or not. By April 9 there was not much further change. The penis measured 6.7 by 3 cm. and the left testis 2.9 by 1.6 cm.; the right testis was a small, hard, cherry-sized nodule in the upper end of the scrotum. The prostate was well developed and about 3 cm. in diameter.

May 28, 1937, after he had had a total of 47,370 units, a small hard right testis 0.7 cm. in diameter was still felt in the upper end of the scrotum, lying attached to the pouch previously described. The penis measured 7.3 by 3.2 cm. and the left testis 2.5 by 1.4 cm. The left testis was at a much lower level and the scrotum was much larger than before treatment was started. July 16, after a total of 55,370 units, the firm hard right testis, about 0.7 cm. in diameter, was still felt in the upper end of the scrotum associated with the pouch already described. The penis measured 7 by 3.2 cm. and the left testis 2.5 by 1.4 cm. The prostate had not changed in size. Erections continued to be very frequent. The pubic hairs were about the same.

At 11 a. m. August 19, after the patient had received a total of 60,570 units, a firm painful swelling about 6 cm. in diameter developed in the right side of the scrotum. This swelling could not be reduced by manipulation. Operative procedures were started at 3 p. m., the usual right herniotomy incision being made. A purplish loop of bowel was found extending down to the extreme upper end of the scrotum and held down at both the external and internal ring. Extending about 6.4 cm. below this loop of bowel was a fluctuant swelling containing about 100 cc. of clear yellow fluid. This represented a marked increase in the size of the pouch previously described. The increase in the fluid was apparently caused by transudation associated with the strangulated hernia. At the proximal posterior end of this fluctuant swelling, just distal to the loop of bowel, was an atrophic white testis measuring about 1.5 by

8. We used two preparations of the anterior pituitary-like principle, follutein of E. R. Squibb and Sons, and A. P. L. of Ayerst, McKenna and Harrison. These were supplied by the respective companies.

0.7 cm. This was larger than the previous estimates. The strangulated bowel was returned to the abdominal cavity. A tunica vaginalis was formed from part of the peritoneal pouch and the testis placed in the scrotum.

Aug. 12, 1936, the patient's basal metabolism was minus 11 per cent. March 6, 1937, it was minus 16 per cent. March 27, 1937, it was minus 10 per cent. His weight increased from

Fig. 1.—Precocious sexual development in case 1: A, July 18, 1936, before treatment, age 6 years 7 months; B, July 24, 1937, after eleven and one half months of treatment with anterior pituitary-like principle (total dose 56,570 rat units).

19.5 Kg. Aug. 12, 1936, to 26.5 Kg. by March 27, 1937. During the same period his height increased from 113.7 cm. to 123.2 cm. March 8, 1937, there appeared to be about normal development of the epiphysial lines of the knees and elbows and on July 30 there was no evidence of any premature closing.

Photographs of this patient during the course of treatment are shown in figures 1 and 2. It is of interest that at the age of 7 years he had a penis larger than that of his father.

CASE 2.—E. W., aged 9 years and 1 month, came to the clinic June 19, 1936, because the testes had not been brought to a sufficiently low level by operative procedures. A right orchidopexy had been done at the Cook County Hospital July 31, 1935, and a left orchidopexy at the same institution Oct. 15, 1935. The position of the right testis before operation was not described. The left testis was said to be in the canal just below the internal ring. On each side the undescended testis was associated with a small hernia. When we first saw the patient each testis was about the size of "a small cherry" and located at the junction of the scrotum and the opening above it. The scrotum was small. The penis measured 4.1 by 2.2 cm. The prostate was barely palpable. The pubic hair was just a fine fuzz. The body contour was normal. Treatment with follutein was started July 27, 1936, and the dose rapidly increased until he was receiving 200 rat units six times a week. Aug. 7, 1936, after he had had a total of 1,520 units, the penis had enlarged to 5.4 by 2.2 cm. and the prostate was about 2.5 cm. in diameter. Erections had become more frequent. There was no definite change in the position of the testes. September 24, after he had had a total of 7,720 units, each testis was the size of "a large cherry" and seemed to be at a slightly lower level. The penis measured 5.1 by 2.7 cm. and the prostate was about 2 cm. in diameter.

October 30, after he had had a total of 12,720 units, the testes were at a definitely lower level than before treatment was started, although still in the upper part of the scrotum. The penis measured 6.1 by 2.7 cm., the right testis 2.5 by 1.6 cm. and the left testis 2.9 by 1.9 cm. The prostate was well defined and about 2 cm. in diameter.

December 11, after he had had a total of 17,320 units, the genitalia had grown still more and the testes were at a slightly lower level in the scrotum, which was enlarging. The penis measured 7 by 3 cm. and the prostate was about 2.5 cm. in diameter. The pubic hairs had grown slightly. By Jan. 15, 1937, after he had had a total of 19,520 units, the penis measured 7.3 by 3 cm., the right testis 3.2 by 2.5 cm. and the left testis 3.8 by 2.5 cm. The prostate was about 2.5 cm. in diameter and there were several pubic hairs as much as 1.2 cm. long. By February 26, after he had had a total of 23,320 units, the penis was about the same size as at the time of the previous examination and each testis measured 3.5 by 2.2 cm. The pubic hairs were as much as 1.9 cm. long. His voice had become lower in pitch, he was very aggressive and his muscles were hard. Erections continued to be frequent. April 9, 1937, after a total of 27,120 units, his scrotum had developed more and his testes were at a lower level. The penis measured 7.6 by 3 cm., the right testis 3.2 by 2.4 cm. and the left testis 3.5 by 1.9 cm. The pubic hair was about the same as on February 26. The prostate was about 2 cm. in diameter. May 28, after a total of 31,520 units, the measurements, except for the penis, which was 7.3 by 3 cm., were about the same. The pubic hair was scanty but as much as 5.1 cm. long. July 16, after a total of 34,720 units had been administered, the penis measured 7 by 2.9 cm., the right testis 2.5 by 1.9 cm. and the left testis 3.2 by 1.9 cm. The pubic hairs were about the same as on the last examination.

His basal metabolic rate was minus 4 per cent June 17, 1936, and minus 5 per cent April 10, 1937. During this period his weight increased from 30.7 Kg. to 38.2 Kg. and his height increased from 139 cm. to 148 cm. Roentgenograms of his knees and elbows taken March 8, 1937, and Nov. 6, 1937, show the development of the epiphyses to be normal.

The effect of treatment in this case is shown in figure 3.

CASE 3.—R. S., a boy aged 4 years and 11 months and of normal body contour, was referred to us by the Pediatrics Department Nov. 23, 1936, because of supposed failure of descent of the left testis. There was a history of undescended testis in a second cousin on each side of the family. The

Fig. 2.—Stages in development in case 1: A, July 18, 1936, before treatment; B, Dec. 12, 1936, after 19,970 rat units of anterior pituitary-like principle; C, April 15, 1937, after 39,970 rat units of anterior pituitary-like principle.

patient was reported to have been born with a swelling "in the region of the right testis," which disappeared soon after the application of heat. At the time of the first examination it was thought that the peritoneal process was felt in the scrotum on the left, but the testis itself was not felt. In view of our subsequent finding of a small atrophic mass on the left side of

the scrotum we are inclined to believe that the testis may have been in the scrotum at the time of the first examination but was not felt because of its small size. However, we must also admit the possibility that the descent of this small atrophic testis may have been produced by treatment. The penis measured 3.8 by 1.6 cm. and the right testis 2.9 by 1.7 cm. Treatment with A. P. L. and maturity factors⁹ was started Dec. 3, 1936. The dose was quickly increased to 200 rat units of A. P. L. and 25 rat units of maturity factors six times a week. December 11, after he had had a total of 1,120 units of A. P. L. and 150 units of maturity factors, the penis measured 4.1 by 2.9 cm. and the right testis 3.8 by 2.9 cm.; the left testis was reported not to be palpable. The prostate was not palpable. Jan. 15, 1937, after he had received 4,320 units of A. P. L. and 550 units of maturity factors, the penis measured 6.7 by 2.1 cm. and the right testis 3.2 by 1.7 cm. We were not certain whether a small mass in the left side of the scrotum represented the left testis or not. The prostate had enlarged and erections had become more frequent. February 18, special strength A. P. L., which contained 500 rat units per cubic centimeter, was substituted for the weaker solution, which contained 100 rat units per cubic centimeter, and by February 23 the dose had been increased to 1,000 units six times a week. The dose of maturity factors remained unchanged. February 26, after he had had a total of 12,520 units of A. P. L. and 1,175 units of maturity factors, the penis measured 5.9 by 2.2 cm. and the right testis 3.2 by 2.2 cm. A small atrophic mass in the left side of the scrotum was thought to be the left testis. The prostate was about 1.5 cm. in diameter and bulged into the rectum. April 9, after he had had 29,020 units of A. P. L. and 1,925 units of

of 55,020 units of A. P. L. and 3,225 units of maturity factors. On this date the penis measured 6.7 by 2.5 cm. and the right testis 3.2 by 1.6 cm. A small nodule in the left side of the scrotum was thought to be the left testis because what seemed like a vas deferens was felt above it. The left side of the scrotum was not as well developed as the right. The prostate bulged into the rectum and was about 2.5 cm. in diameter. Pubic hair was as much as 3.8 cm. long. Although there was

Fig. 3.—Precocious sexual development in case 2: A, June 19, 1936, before treatment; age 9 years 1 month; B, July 31, 1937, after one year of treatment with anterior pituitary-like principle (total dose 35,920 rat units).

maturity factors, the penis measured 7.3 by 2.4 cm. and the right testis 3.8 by 2.1 cm. The scrotum was unusually well developed for his age. On the left side of the scrotum was a small nodule about 0.4 cm. in diameter which was thought to be the left testis. The prostate was full and measured about 3 cm. in diameter. There had been a definite growth of pubic hair, which was as much as 2.5 cm. long. The patient missed some of his appointments, but by July 16, 1937, he had had a total

9. We used the anterior hypophyseal maturity factors (gonadotropic) of Ayerst, McKenna and Harrison.

Fig. 4.—Precocious sexual development in case 3: A, Dec. 2, 1936, before treatment; age 4 years 11 months; B, July 17, 1937, after seven and one-half months of treatment with anterior pituitary-like principle (55,020 rat units) and gonadotropic maturity factors (3,225 units).

some hair on the sides of his face, it was uncertain whether it had increased any with treatment. His voice seemed husky, but the mother was unwilling to admit that any change had occurred. She also stated that there had been no change in the patient's virility.

From Dec. 2, 1936, until April 10, 1937, four basal metabolic rates varied from plus 1 to minus 10 per cent. During this period his weight increased from 20.1 Kg to 22.3 Kg, and his height from 112 cm. to 114 cm. March 9, 1937, the x-ray department reported that the ossification center for the capitellum was present in the elbows. No other ossification centers were seen. All the ossification centers were present in the knees and were fairly well developed.

The effect of treatment in this case is shown in figures 4 and 5.

COMMENT

In all these patients the marked increase in the size of the penis, scrotum and prostate and the development of pubic hair furnishes a striking contrast to the absence of a clearcut increase in the size of the testis. At the end of treatment the testes were small in comparison with other parts of the genitalia. In this respect, our results were similar to those obtained in animal experiments.

The growth of pubic hair was more marked in case 1 than in the other cases.

In all cases the response to the stimulus was prompt. In case 1 the penis grew 1.3 cm. in forty-eight days, although the patient had received only 7,570 units of

follutein. In case 2 the penis increased 1.3 cm. in eleven days, although a total of only 1,520 units of follutein had been administered. In case 3 some increase in the size of the penis was noted in eight days, although only 1,120 units of A. P. L. and 150 units of maturity factors had been administered.

The growth of the genitalia seemed to reach a maximum quickly. In case 1 the penis was about as long after only a little more than four months of treatment as at the end of eleven months, in case 2 it was about as large at the end of four and one-half months of treatment as at the end of eleven and one-half months, and in case 3 it was nearly as large after one and one-half months of treatment as it was at the end of eight and one-half months.

The fivefold increase in the strength of A. P. L. in case 3 did not seem to exert any greater influence on the size of the genitalia than the smaller dose. In several other cases we have been impressed by the marked susceptibility to this growth stimulus, the striking increase in size of the genitalia occurring with

show marked development without much change in the seminiferous tubules, and the activity of the interstitial cells seems to be responsible for the development of secondary sexual characteristics. The marked growth in other parts of the genitalia with little or no increase in the size of the testes may be consistent with the hypothesis that in the testis the anterior pituitary-like principle stimulates primarily the interstitial cells. Increased activity of the interstitial cells of the testis may be responsible for the growth of the penis, prostate, scrotum and pubic hair. From a biologic point of view, the problem is whether this material (or a related substance) is involved in normal puberty or whether it merely mimics the changes that occur during this period. If it is involved, it must be only one factor, because normal development of the testis apparently cannot be explained by the presence of this material alone. In view of its production in large quantities in the early months of pregnancy, it is pertinent to inquire whether it plays an essential role in the early development of the genitalia.

Premature puberty is said to be produced in man by tumors of the adrenal cortex and pineal gland and occasionally by tumors of the testes and lesions of the midbrain.¹⁰ Its relation to pituitary¹¹ disturbances is open to question. There are cases which can be explained only by a marked familial tendency to precocious development.¹² In animals, thymus extracts are reported to be powerful sex stimulants.¹³ It would

Fig. 5.—Close-up of genitalia in case 3: A, Dec. 2, 1936, before treatment; B, July 17, 1937, after 55,020 rat units of anterior pituitary-like principle and 3,225 units of gonadotropic maturity factors.

comparatively small doses. On the other hand, it cannot be concluded that there is a lack of susceptibility to the stimulus unless very large doses (from 2,000 to 2,500 rat units daily) are administered.

It is to be noted that although this material produced descent of the right testis in case 1, it failed to correct the associated congenital abnormality: the hernial pouch. This grew into the scrotum as the testis descended and failed to become obliterated, as happens in normal development, to form the tunica vaginalis.

The susceptibility of the genitalia to this growth stimulus appears to be greater before than after puberty, but even after puberty it is not completely absent. We have produced genital growth by the use of this material in a child as early as the age of 3 years and in a man as late as the age of 37 years. The various factors which influence the susceptibility of the genitalia to it and the mechanism of its action are not precisely defined. We do not know whether spermatogenesis occurred in the subjects of this study or not. In case 2 no spermatozoa were found in one examination of the seminal fluid. From observations in man and animals it would appear reasonably well established that in the male the interstitial cells may

be desirable to know whether the mechanism involved in the production of premature sexual development in these pathologic conditions is similar to the mechanism involved in its production from the administration of the anterior pituitary-like principle.

The association of premature puberty with interstitial cell tumors of the testis is of interest, in view of the fact that the anterior pituitary-like principle is known to stimulate the interstitial cells. It is also of interest that, in patients showing precocious development of the genitalia associated with tumors of the adrenal cortex, the testis shows little or no increase in size and spermatogenesis apparently does not occur.¹⁴ The absence of a familial tendency in the cases reported in this paper, the failure of careful examination to reveal any of the other known causes of premature development, and the prompt response of the genitalia to treatment in these and many other cases leave little doubt that genital growth was caused by the anterior pituitary-like principle.

These data serve as a warning against the indiscriminate use of this material in patients with undescended testes. It has been shown elsewhere that it has a very definite role in the treatment of this condition, but the patients receiving it must be followed carefully and its administration stopped before genital growth becomes excessive.

It is too early yet to know what influence, if any, precocious sexual development caused by this material exerts on skeletal growth. The fact that bone development was normal in the three cases reported does not mean that it will continue to be.

SUMMARY

Changes simulating premature puberty have been produced in three boys, 4, 7 and 9 years old, by the administration of the anterior pituitary-like principle from the urine of pregnant women. These changes consisted of an increase in the size of the penis, scrotum and prostate, increased masculinity, a growth of pubic hair and a change in the pitch of the voice.

In contrast to the marked growth of other parts of the genitalia, the testes showed very little change in size. All the boys were of normal body contour and had a normal sized penis before treatment was started. The boy 4 years old had an atrophic left testis which did not increase in size with treatment. The other two boys had undescended testes and in one of them an unsatisfactory attempt at surgical correction had been made. In both patients the testes descended to the normal position with treatment.

Some genital growth has been produced with this material in sixteen of thirty-three patients with undescended testes, and in fourteen patients, including two of the three boys who developed changes simulating premature puberty, it was marked. However, descent was produced in only 23 per cent of the total number of undescended testes, showing that genital growth may occur without descent of the testis.

The treatment for undescended testes with the anterior pituitary-like principle should be stopped before genital growth becomes marked. If this rule is followed, it would appear that in the present state of our knowledge its routine use is justifiable and desirable.

RENAL MOBILITY

ELMER HESS, M.D.

ERIE, PA.

Renal mobility has been studied for years. Albarran was perhaps the first to notice clinically that immobility of the kidney during respiration was a helpful diagnostic sign in perinephritis with adhesions to the renal fascia.

In 1925 and for many years since then, Mathé has called attention to the lack of normal motion in certain perirenal inflammatory conditions and perhaps was among the first, if not the first, to take advantage of the fact that the pyelogram taken in the erect posture and a second pyelogram taken in the prone posture would show limitation of renal motion and would aid him in the diagnosis of many obscure perirenal pathologic conditions.

About a year ago, following five years of observation, Hilgenfeldt reported a study of renal mobility. He took pyelograms in both the prone and the upright position, in deep inspiration and expiration in the prone

Fig. 1 (case 1).—Excessive respiratory mobility. Both kidneys within normal limits.

position, and studied the variations in kidney position under various types of pathologic conditions. These observations have often been extremely helpful in diagnosing obscure lesions involving pathologic changes in and around the kidney.

About a year ago Dr. Ralph Bacon, who with his associate Dr. B. Swayne Putts does all the roentgenologic work in the urologic department at St. Vincent's Hospital, suggested an inspiration and expiration pyelogram on the same film in the study of some of our difficult diagnostic problems. He had become convinced of the value of such a study after several years of close cooperation with the urologic service and suggested to me that such an extra pyelogram might be of great value in our work. On my recalling to him Mathé's earlier work on the postural movement of the kidney, he began to search the literature for any light that it might give us on this subject. He found that Chevassu in 1933 reported a case of perinephric infection in which during fluoroscopy he was satisfied that the contrast filled kidney pelvis appeared absolutely motionless during deep inhalation, that Mathé had demonstrated lack of renal mobility in perinephric

President's address, read before the Section on Urology, Pan American Medical Association, Havana, Cuba, Jan. 17, 1938.

infection, and that Hilgenfeldt had written his comprehensive report. Other than this the literature had little to offer with the exception of a report by myself given in a discussion before this society in July 1931 on renal sympathectomy at Mexico City. At this time I mentioned that the pyelogram taken in inspiration and expiration would demonstrate the nonfixation of the normal kidney and that after the sympathectomy, because of adhesions between the capsule and Gerota's fascia, the kidney could be placed in whatever position the operator desired. These facts had been demonstrated by pyelography:

In movable kidneys as well as in others, after operation, the kidney will be found to be fixed in a fairly high position by the surrounding adhesions. There will be practically no mobility and the ureter will be found straight and upon checking in the sitting or upright position the kidney will not descend nor will the ureter kink. As a matter of fact, if the kidney descends several inches before the adhesions form, and becomes fixed in a low position, it will no longer give symptoms. It does not matter really just where the kidney becomes fixed postoperatively just so it is fixed and its ureter is straight and not kinked.

It is plainly evident that renal mobility has not been given the consideration in the study of urologic problems that it justly deserves. The kidneys are loosely fixed by vascular pedicles, aberrant vessels, fascias, fatty beds and intra-abdominal pressures and are therefore rather freely movable under normal conditions. Posture always causes definite changes in their positions. Breathing has a distinct bearing on their mobility, both in the upright and in the prone positions. Various intraperitoneal and extraperitoneal pathologic conditions will have a direct bearing not only on the position of the organs but on their mobility as well. Thoracic disease will likewise influence both position and mobility. Pathologic and congenital abnormalities of the kidneys themselves will influence to a marked degree both position and movability. Anything that can establish a normal position and normal movements of the organs, together with comparison studies of abnormal positions and movements, must be an aid in diagnosis and will be a distinct help in the planning of any surgical procedure contemplated.

I have been interested in the study of renal position and mobility for years and, as more and more opportunity has been afforded for the study of these phenomena, definite conclusions have become logically evident. Many of these will of necessity have to be modified as time goes on and more experience is gained, but a review of some personal experiences may at this time prove stimulating.

RESPIRATION PYELOGRAPHY

Dr. Bacon has coined the word "respiration pyelography" and I am now using it more or less as a routine, particularly when I have a patient who will intelligently cooperate.

TECHNIC

With the catheters in place we first take a plain roentgenogram followed by a plain pyelogram with the patient simply holding his breath, after which we use a third film with a fast cassette. The patient is now instructed to take a long breath and hold it and the first exposure is made. The patient then is instructed to exhale completely and remain quiet while the second exposure is made on the same plate. These pyelograms are all made in the prone position.

First I wish to discuss normal respiration pyelography. The one striking feature about these cases is the

apparent kinking of the normal ureter in deep inspiration and the occasional movement that takes place laterally in pyelograms that we consider normal. It must be remembered that a urogram that shows a kink in the ureter with normal pyelographic shadowing and cupping must be interpreted as a kink only after it is known whether the pyelogram was made in deep inspiration or expiration. I think these pyelograms show the necessity for great care in the interpretation of ureteral kinks. Surely a respiration pyelogram will quickly show whether these tortuosities have any real pathologic significance.

The diaphragm should move normally when deductions are made of renal mobility and fixation. If the diaphragm is immobilized by intrathoracic or by pararenal pathologic conditions, the kidney will not move in respiration. If for any reason it becomes necessary to section any nerves such as the intercostal groups, if thoracoplasty is necessary or vagus nerve injuries are

Fig. 2 (case 4).—Normal renal mobility.

encountered, these of course will all influence renal mobility because of the paralysis of the diaphragm.

According to Hilgenfeldt, kidney displacement is not entirely dependent on the movement of the overlying diaphragm but depends somewhat on the abdominal muscles, the opposite diaphragm and the attachments of the prerenal fascia to the duodenum and colon. As these organs move with the diaphragm the ureteral attachment to the postparietal peritoneum several centimeters below the renal pelvis may likewise be influenced by the movement of these structures. Therefore a fluoroscopic study of the diaphragmatic movements in inspiration and expiration is essential.

RESPIRATION PYELOGRAPHY SHOWING NORMAL MOBILITY OF THE KIDNEYS

CASE 1.—C. D., a woman, aged 42, admitted to the urologic department at St. Vincent's Hospital Dec. 7, 1937, complained of pain in the left lower abdominal quadrant. Pus cells were found in the urine. She had a stricture of the lower left ureter which might be spastic and not inflammatory in character. Cultures from the left kidney yielded a staphylococcus.

Normal pyelograms showed some blunting of the calices on the right side, although this was symptomless and normal. Every picture showed spasticity of the right renal pelvis.

A respiration pyelogram showed normal mobility of the right kidney and considerable mobility of the left kidney with some definite lateral movement. This picture (fig. 1) is shown to point out two facts: first, that, if a picture is taken in deep inspiration, what is normally thought to be a ptotic kidney might prove to be a perfectly normal kidney if taken in deep expiration; second, to show also the marked normal motion in deep respiration of a reasonable normal organ.

CASE 2.—M. A. G., a woman, aged 32, admitted Dec. 13, 1937, gave a history of pain in the right side typical of renal colic, with slight bladder disturbances on voiding. The pain was sufficiently severe to require severe hypodermics. There was no history of menstrual disturbances or vaginal bleeding. The preoperative diagnosis was calculus, right ureter.

Pyelograms by Dr. Putts did not reveal any calculi. The right pyelogram gave a normal picture. The left pyelogram showed a smaller pelvis with calices and their terminals changed, suggesting a chronic infection. Tuberculosis had to be considered. Both kidneys were prolapsed 2 inches. The ureters in the pelvis appeared pushed outward, more than normal, probably because of the soft tissue mass noted.

Fig. 3 (case 10).—Normal renal mobility probably demonstrating an aberrant vessel.

There was a definite obstruction in the lower right ureter. Pelvic examination revealed a mass irregularly nodular and immovable, filling the entire pelvis.

The final diagnosis was inoperable carcinoma of the pelvic organs with beginning obstruction to the right ureter from the mass.

Respiration pyelograms showed considerable movement and fairly normal kidneys.

CASE 3.—W. B., a man, aged 42, an outpatient, admitted to the urologic department at St. Vincent's Hospital July 22, 1937, had a bad stricture of the urethra with some dilatation of the posterior urethra and hypertrophied dilatation of the bladder. A normal pyelogram was made which was essentially negative. A respiration pyelogram was made which showed normal mobility on both sides without any dilatation of the upper urinary tract from the stricture.

CASE 4.—Sr. F. X. came to the hospital Nov. 8, 1937, with the diagnosis of possible tuberculous nephritis. For some time organisms resembling the tubercle bacillus had been found in the specimens of urine, although she had never had any direct symptoms. Examination revealed fairly normal kidneys and a normal bladder. A respiration pyelogram (fig. 2) showed normal motion. The organism diagnosed as the tubercle bacillus was later identified as the smegma bacillus.

CASE 5.—R. S., a woman, aged 32, admitted July 12, 1937, complained chiefly of frequency and urgency of urination and pain in the left part of the back. Cultures of urine from the

left kidney yielded a colon bacillus; from the right kidney no culture. A diagnosis of left pyelonephritis with some nephrosis was made. The respiration pyelogram showed bilateral motion on both sides, which was considered virtually normal.

CASE 6.—M. M., a woman, was admitted July 20, 1937, with the diagnosis of bilateral pyelonephritis with normal movement.

Pyelograms by Dr. Bacon did not reveal opaque calculi. The pyelograms appeared normal except for a slight nephrotic change on the left side.

CASE 7.—M. S., a woman, aged 38, was admitted July 20, 1937, with the diagnosis of bilateral pyelonephritis, more marked on the right side.

Pyelograms by Dr. Bacon revealed no evidence of opaque calculi. The pyelograms appeared approximately normal.

A respiration pyelogram revealed normal movement.

CASE 8.—J. S., a man, aged 37, admitted Aug. 2, 1937, complained of smarting and burning in the rectum and penis. Three large stones were found in the bladder.

Pyelograms by Dr. Putts revealed three calculus-like shadows in the bladder region. The right pyelogram was normal. Slight dilatation was noted in the pelvis of the left kidney. The calices were also slightly changed, so that some nephrosis was indicated.

A respiration pyelogram was essentially negative with normal movement.

CASE 9.—C. M., a man, aged 47, admitted July 14, 1937, had bloody urine and pain in the left hypogastrium and the left loin. The diagnosis was bilateral pyelonephritis.

Pyelograms by Dr. Putts did not reveal any calculi. The pyelograms were approximately normal.

A respiration pyelogram revealed normal renal movement.

I have selected this series of cases which demonstrate the normal movement of the kidneys in deep inspiration and deep expiration and which show that there was no perirenal or pararenal pathologic condition and that if there was it had not involved the capsule of the kidney or the fascia about the pelvis and the ureter. Several of these cases, however, have been diagnosed as bilateral pyelonephritis but the inflammatory condition is limited to the kidney itself.

RESPIRATION PYELOGRAPHY AS CONCERNS ABERRANT VESSELS

If an aberrant vessel to the lower pole of a kidney is the cause of a nephrosis, or if bands in the periureteral fascia are the cause of kinks at the ureteropelvic junction, a respiration pyelogram should be of considerable value in helping to make the diagnosis.

CASE 10.—A. D., a woman, aged 28, admitted July 19, 1937, complained chiefly of intermittent pain in the right side with considerable functional bladder disturbance. Cultures from both kidneys yielded colon bacilli. The cystoscopic and pyelographic diagnosis was right hydronephrosis, probably due to an aberrant vessel causing a constriction at the ureteropelvic junction on the right side.

A respiration pyelogram (fig. 3) seemed to emphasize this kink, although there was plenty of motion in the kidney and a kink also appeared on the left side during deep inspiration, although it was completely obliterated during expiration. It was believed that the possible limitation of motion of the right side as compared to that of the left may be accounted for by an aberrant vessel. This, it was considered, might not be an aberrant vessel but might be due also to fibrous bands. Operation was not performed.

Careful study of this pyelogram will show that the kink at the ureteropelvic junction is very much emphasized on deep inspiration, although the kidney moves virtually normally in the respiration pyelogram. It is my belief that in this case we are dealing with an aberrant vessel, although the patient has not come to operation for verification of that diagnosis.

Where infections such as carbuncles, multiple cortical abscesses and other lesions which extend from the parenchyma of the kidney to the capsule and through the capsule are found, there will be a definite limitation of motion on the affected side as compared to that of its fellow. This is ably demonstrated by case 11:

CASE 11.—H. R., a man, aged 69, was admitted Nov. 20, 1937, with a history of recurrent attacks of severe right-sided loin pain and some hematuria.

Fig. 4 (case 12).—Perinephric abscess behind and above kidney

Pyelograms revealed no evidence of calculi. The left pyelogram was approximately normal. The pelvis and calices on the right side together with the upper end of the ureter were somewhat changed, almost lead-pipe in type. An area of destruction was noted in and beyond the median calix and in the upper outer part of the inferior calix. The appearances suggested a destructive lesion which would be best explained by neoplasm or infection, most likely tuberculous.

A respiration pyelogram was made showing fairly normal movement of the left kidney, while the right moved probably 60 per cent of normal. Fluoroscopy showed that the diaphragms moved freely. The urologic opinion on this case was that there was a chronic inflammatory disease of the kidney, probably tuberculous, although neoplasm could not be ruled out. As a result of what we consider a partial limitation of motion it was considered that this kidney had some perirenal inflammatory adhesions more or less fixing it. At operation the presence of marked perirenal adhesions was noted and the condition in the kidney was neither tuberculous nor neoplastic but was due to a badly infected infarct.

This fixation is further exemplified by perirenal abscess formation. Whether the perirenal abscess is caused by a coalescence of cortical abscesses extending through the capsule into the perinephric fat or whether it is caused by emboli of organisms in the vessels of the perirenal fat and is primary there is of little moment.

In these cases the diagnosis may be made fairly early. The diaphragm will not be limited in its motion but the kidney will be as soon as the infection fixes the capsule of the kidney to Gerota's fascia, or as soon as the kidney is immobilized by an abscess within Gerota's fascia. This is beautifully demonstrated by case 12:

CASE 12.—A. P., a man, aged 36, admitted to the urologic department at St. Vincent's Hospital Dec. 7, 1937, had been in the hospital for a considerable time with an undiagnosed

septic condition. He was transferred to the urologic service for check-up and survey. Cultures from the urine of the right kidney yielded the staphylococcus.

Pyelograms revealed no opaque calculi. The right psoas shadow was obliterated and the renal shadow on this side could not be made out. The pyelogram on the left was normal. The pyelogram on the right showed evidence of slight nephrosis. The pelvis on the left side was 5 cm. from the midline; on the right side it was 7 cm. away and had the appearance of being depressed along its upper surface. Similarly the hepatic flexure of the colon was displaced inward and downward. Slight haziness overlay the entire upper right quadrant. Fluoroscopy of the diaphragm showed that both sides moved slightly but within normal limits.

Respiration pyelography by Dr. Bacon (fig. 4) showed that the left kidney moved downward 1.6 cm. during the respiratory phase. The right kidney moved downward 0.3 cm. and outward about the same distance. This lack of craniocaudal movement is indicative of a perinephric infection on the right, behind and above the kidney.

It will be noted that the diaphragms move freely but that the kidney is anchored in position as a result of the collection of pus within Gerota's fascia. The large colon can be seen pushed toward the midline.

In contradistinction to the diagnostic information that can be obtained from a respiration pyelogram in perinephric abscess are the findings of a paranephric collection of pus. In the subdiaphragmatic collections of pus the diaphragm is fixed; therefore there is no motion of the kidney in the respiratory pyelogram, either laterally or up or down. This is a splendid differential diagnostic point and the following case demonstrates this:

CASE 13.—M. L., a girl, aged 15, admitted to the urologic department Nov. 11, 1937, had been in the hospital for a considerable period with an undiagnosed elevation of temperature. A pararenal abscess was finally considered as the diagnosis.

Fig. 5 (case 13).—Subdiaphragmatic abscess. Diaphragm does not move. Kidney does not move.

Pyelograms revealed no evidence of opaque calculi. Slight blunting of the superior minor calix was present in the right kidney. The pyelograms were otherwise normal.

A respiration pyelogram (fig. 5) by Dr. Bacon demonstrated 1 cm. of motion of the left kidney and no motion of the right kidney. The lack of motion of the right kidney was ascribed to the previously described immobilization of the right diaphragm, which had been present throughout the weeks of study.

On several occasions prior to the urologic study the right diaphragm had been completely immobilized. Owing to the fact that the right kidney did not move in either inspiration or expiration and the fact that the right diaphragm likewise did not move, it was considered that movement of the kidney was not due necessarily to perinephric pus or adhesions but that in all probability it was due to paranephric pus.

The final diagnosis was subdiaphragmatic abscess.

Hilgenfeldt calls attention to the value of postural and respiration pyelography for the localization of foreign bodies, such as calculi in the kidney pelvis and ureter. However, under ordinary circumstances this localization can be made by simple pyelography, although confirmation of the deductions will be more accurate if the respiration pyelogram is used.

Bacon, working with us and in ignorance of both the work of Hilgenfeldt and Mathé, says:

My interest in the problem was initiated nearly a year ago by a case in which I was able to demonstrate fluoroscopically absolute lack of motion of the posterior half of the inferior margin of the liver in a male patient, 7 years of age, who was

ing is largely diaphragmatic or costal; the length of the renal pedicle may play a part. The mobility of the two kidneys is not necessarily the same. It follows that diaphragmatic motion must be normal in order to judge kidney mobility by respiration pyelography.

At the time he wrote this there had been no case of paranephric infection available for this study but since then we have had a case.

Bacon further says:

However, other conditions may cause perirenal fixation. In his perirenal sympathectomy for painful nephroptosis, Hess dissects the kidney free from the fascia, removes the nerve and lymphatic tissues from about the kidney pedicle and strips the ureters clean. He then replaces the kidney in its normal fossa but does not do nephropexy. In studying four of his patients who have been thus operated on, we have demonstrated complete immobility of the postoperative kidney in three and partial fixation in the fourth patient. Our explanation is that adhesions about the pedicle and particularly between the capsule and perirenal fascia are responsible for this fixation.

RESPIRATION PYELOGRAPHY AS A CHECK-UP ON RENAL POSITION AND MOBILITY AFTER SYMPATHECTOMY FOR OPERATIVE RELIEF OF PTOTIC KIDNEYS

When after careful study we decide that the patient is a proper subject for surgical procedure because of renal ptosis, we always do a renal sympathectomy without decapsulation and without making any attempt to do any of the operative procedures which would class the operation as a nephropexy. A review of several of our papers will explain our reasons for not doing a nephropexy.

CASE 14.—H. C., a man, admitted Sept. 25, 1937, had a right sympathectomy March 2, 1937, for pain in his right side, which was diagnosed as a nephroptotic kidney giving symptoms.

A pyelogram by Dr. Putts revealed no calculi. Part of the right twelfth rib had been removed. Double pyelograms on deep inspiration and expiration showed that movement of the right pyelogram was 1.5 cm. and 5.5 cm. on the left side. The right diaphragm had moved 3.5 cm., while the left diaphragm had moved about 1.5 cm. Pyelograms appeared approximately normal.

There was very slight up and down movement in the respiration pyelogram on the sympathectomized side and a very marked difference on the left side.

CASE 15.—E. H., a woman, aged 24, was admitted Aug. 30, 1937, for a check-up following a renal sympathectomy on the right kidney done about two months previously. She had a definite nephroptosis causing symptoms sufficient to warrant operation. She had been under observation for about eighteen months prior to operation and we felt justified in attempting to correct the ptosis in this organ. The x-ray report prior to operation was right kidney 2 inches below its usual position with a very tortuous ureter. A pyelogram was approximately normal.

A respiration pyelogram showed the kidney fixed high in the renal fossa with a straight ureter with no up and down motion during deep inspiration and deep expiration but a slight lateral motion. The patient was completely relieved of her symptoms.

CASE 16.—F. S., a woman, aged 32, admitted Sept. 1, 1937, had had constant severe right-sided renal pain. She had been admitted to the hospital on several occasions during the past four years, with a diagnosis of right nephroptosis causing symptoms. She received complete relief from her right nephroptosis when she wore a proper supporting garment. However, she finally decided that she would rather be operated on. The operation done some six months prior to the present study consisted of a simple periaarterial sympathectomy with ureterolysis.

Fig. 6 (case 16).—Renal sympathectomy.

admitted to the hospital with complaints of three weeks' duration: fatigue, lassitude, afternoon temperature rise, and slight pain in the right lumbar region. White blood cells on admission, 26,500.

Roentgen study on Nov. 7, 1936, showed a liver shadow enlargement on the right side with slight diaphragmatic elevation; diaphragmatic motion was normal. During fluoroscopy, the lower margin of the liver stood out sharply; the posterior half exhibited no motion on respiration. Because of these findings plus the clinical evidence, a tentative diagnosis was hazarded of a disease process involving the posterior inferior surface of the liver.

Operative findings: An upper pole perinephric abscess.

Because of this case he studied the mobility of the kidney in extremes of expiration and inspiration in our clinic. We have cooperated with him much to our satisfaction in the diagnosis of many of our difficult problems.

He says again:

After the kidney pelvis is filled with contrast material, preferably by retrograde pyelography, a film is exposed twice, once on deep inspiration and once on forced expiration. The normal pelvis therefore casts two shadows and the distance between them represents the normal respiratory excursion in the horizontal posture. The average is 3.7 cm. but there may be considerable variation depending primarily on whether breath-

The respiration pyelogram done September 1 (fig. 6) showed the normal movement of the left kidney and distinctly showed the high position of the right kidney with a slight lateral movement on deep inspiration and deep expiration. There was no up and down motion.

COMMENT

In all these cases I would call attention to the straightness of the ureter, the high position of these kidneys and the lack of mobility of the organ that has been operated on as demonstrated by respiration urography, comparing its movement with that of the opposite kidney. There is only a slight up and down motion but there is a distinct lateral motion to the sympathetomized kidney.

I have not made the slightest attempt to hook the ptotic kidney to a rib or to fashion any other type of nephropexy support for the kidney, nor to decapsulate it. The sole procedure has been a periarterial sympathectomy with ureterolysis, extending as far into the pelvis as possible. I wish also to call attention to the fact that there has been no increase in any nephrosis that may have been present prior to operation, but that in some cases there seems to be a distinct return to the normal tonicity of the pelvis and ureter as evidenced by pyelography.

I used to make a hammock of the fascia after the technic of Deming in these cases; I used to decapsulate the kidney and I used to do nephropexy, but I think the demonstration that I have presented will prove beyond any question of doubt that it is not necessary to do any fastening by any technic on the operated organ high in the renal fossa; and I do not believe that I need any more conclusive proof that these extra procedures are unnecessary than the demonstration which I have just given. Nephropexy of any type, decapsulation and hammocking all add to the length of the operative procedure and have a tendency to destroy some renal substance, and decapsulation will at times prove a boomerang to the efficiency of the kidney later on. This has, I think, been proved by Rolnick in his recent work on the renal capsule.

In 1924 I advocated periarterial renal sympathectomy for nephroptosis. Based on my experiences in a great number of operative procedures on ptotic kidneys, I now feel that I can offer the profession the simplest efficient technic for the operative control of the ptotic kidney requiring surgical intervention.

Prior to 1930 the position and mobility of the kidney had been studied in our clinic by taking separate pyelograms in deep inspiration and expiration to check our work and results in ptotic kidneys on which sympathectomies had been done.

Hilgenfeldt's studies in the last six years, reported a year ago, have verified all my observations, and he has further used the procedure in the diagnosis of the localization of foreign bodies, for the recognition and differentiation of inflammatory diseases of the kidney and adjacent tissues, for paranephric abscess, kidney carbuncle and pyelonephritis, and the association of kidney location to inflammatory diseases in adjacent tissues, such as pancreatitis, appendicitis and tuberculosis.

Mathé should be given credit for his postural studies of kidney mobility in the diagnosis of perirenal infections.

Further study by respiration pyelography with operative verification of the results will more completely establish the value of the procedure.

CONCLUSIONS

1. Respiration pyelography should be used for the verification of the results on the kidney obtained after operative measures planned for kidney fixation.

2. The technic is simple and inexpensive.

3. Many problems of a clinical nature will be more easily solved and our knowledge of the normal and abnormal mobility of the kidney in both health and disease will be increased by the observations of those who adopt respiration pyelography as a routine procedure in their urologic diagnostic work.

INTERSEXUALITY

WILLIAM H. RUBOVITS, M.D.

AND

WILLIAM SAPHIR, M.D.

CHICAGO

The mechanism that normally governs the differentiation of the two sexes is not fully understood. It is accepted, however, that the sex of the individual is determined at the time of fertilization.¹ The union of maternal and paternal cells is considered the determining factor in the development from the embryonic bisexual "anlage" into either ovaries or testicles under the guide of the endocrine system. If such normal development—for reasons entirely unknown to us—is disturbed during any time of the embryonic life, one encounters as the product of such faulty development the anatomic picture of the intersex.

It is not intended here to enter into a review of the voluminous literature, which since von Neugebauer's² fundamental work in 1908 has increased steadily, but to refer briefly to a few communications pertinent to this study. A convenient review of the newer literature may be found in the recent publication by Huggins, Cohen and Harden.³

In this paper we present a case of intersex that was closely studied clinically, physiologically and psychologically. We report the case not only for its rarity but also because we believe that some facts of interest were found that may clarify this syndrome more definitely and may be helpful in recognizing milder grades of similar clinical manifestations.

REPORT OF CASE

History.—Miss V. D., aged 39, admitted to the Michael Reese Hospital Nov. 9, 1936, had never been sick before. The family history was irrelevant. The patient stated that, since the age of 12, increasing hair growth, deepening of the voice and conversion of the external genitalia to the present stage had gradually developed. She never had menstruated but had had two vaginal bleedings of two hours' duration at the ages of 17 and 20. In association with these progressing bodily changes marked sexual desire toward the male sex developed. In an attempt to satisfy this desire she masturbated a great deal. The patient sought medical attention for relief from the annoying libido, which precluded sleep and ability to work.

Examination (abbreviated).—The patient was well built and well nourished with a dark complexion and a fairly heavy growth of hair on both cheeks, the upper lip and chin, partly

removed, with scar formation, by electrolysis. There was a virile hair distribution of the body. The voice was harsh but neither masculine nor feminine. The breasts were flat, the nipples were atrophic and no glandular mammary tissue was palpable. The external genitalia are shown in figures 1 and 2. The right labium was of considerable size and resembled a scrotum, in which an apparently normal testicle was felt. The left labium appeared smaller. In the left upper labium and inguinal

Fig. 1.—Genital structures: hypospadic penis, and rudimentary vagina between scrotal sacs.

region a similar smaller testicle was palpable. The clitoris had the distinct appearance of a penis 4 cm. long with prepuce, preputial sac and smegma present but no urethral orifice in the glans. The introitus vaginae was 0.75 cm. below the rudimentary penis, flanked by rudimentary labia minora, 1.5 cm. deep and funnel shaped, in the upper portion of which the urethral orifice was found. This structure secreted abundant mucus. On rectal examination a small structure at the neck of the bladder resembling a prostate was palpable, but neither uterus nor adnexa were felt; there was no mass palpable and no uterus or adnexal structures. Physical examination otherwise was negative.

Laboratory examination revealed that the urine, blood count, and chemistry of the blood were normal; the Wassermann reaction was negative. The blood pressure was 108 systolic, 70 diastolic. The sugar tolerance after 100 Gm. of dextrose orally was: fasting 82, one-half hour 192, one hour 177, two hours 170, three hours 81. The metabolic rate was 9 plus. Quantitative titration of the urine for gonadotropic substance revealed an excretion of 333 mouse units per liter by the Zondek alcohol precipitation method.⁴ There was no increased excretion of estrogen as judged by a negative Allen Doisy test with 6 cc. of urine.

The x-ray examination (transabdominal pneumoperitoneum) revealed that the pelvis was small and of the male type. There was no radiologic evidence of internal female genitalia.

Psychiatric Examination (by Dr. Jacob Kasanin,⁵ November 10).—"The patient was well built, well nourished and middle aged with decidedly masculine features, dark complexion and evidences of a fairly heavy growth on both cheeks, which has

been controlled by various depilatory methods and electrolysis. In manner, however, the patient was very feminine, pleasant, gracious, sweet and at times rather coy and somewhat coquettish. She spoke rapidly but clearly. She frequently interrupted her speech by laughter, gesticulated freely, and at times would become quite emotional, and one was given the impression of a somewhat masculine girl or an extremely effeminate man. The voice was rather harsh, but one could not state definitely whether it was masculine or feminine.

"The patient stated that she was born in a small village on a farm, the oldest of five children. Her father kept an apiary and was a fairly prosperous farmer. The mother was kind and sweet and liked the patient very much. Both parents, however, paid very little attention to the children. The patient stated that she was a quiet, sweet, obedient child; she was so good that her mother thought she would become a nun. She played with girls, liked to play with dolls and in every respect was a typical girl. She went to public school, which she completed at the age of 14. At 17 she entered a teacher's seminary. Shortly after this she discovered her physical anomaly and ran away from home. She consulted a specialist, who advised her to wait a few years until it became clearer what her sex was. Meanwhile, the war broke out and the patient entered a hospital as an attendant. She stated that she remained in the hospital several years, until the war was over, and then taught school for three years. For a time she clerked in stores.

"In 1926 the patient came to Chicago and since then has worked as a salesgirl in one of the large department stores.

"The patient stated that at the age of 13 she fell in love with a very good looking boy in her class; he courted her a good deal and brought her cakes and sweets to school and carried her books. The patient was never aware that she was different from other girls until she was 17, when she began to go swimming with other girls. While undressing she had a chance to see other girls and saw that she was different. She became extremely furious with her mother 'because she bore me like that,' so she ran away from home and has never been home since. She changed her name and came, under this assumed

Fig. 2.—Prepared for operation, showing vaginal orifice.

name, to the city. Her parents died without seeing her. She never maintained contact with her family, but she heard about them from time to time through a mutual friend.

"When she was in the hospital during the war, she had many light flirtations with soldiers and officers. They frequently excited her, but she never had intercourse, not because she did not want to but because she was afraid they would discover that she was not like other girls. The patient stated that she 'misstruated' twice in her life. Once when she was 17 she 'found

5. Dr. Kasanin is director of the Department of Psychiatry, Michael Reese Hospital.

her undergarments saturated with blood,' and then again when she was 20. She stated that she had a penis which was about half the size of a man's penis and protruded from the lower part of the abdomen. She stated that it never showed any activity and that no matter how much she was excited sexually she never had an erection. She tried to induce erection in the penis by masturbating and handling it in every possible way, but without success. She had a great deal of erotic feeling under the penis, 'where the water comes from,' and she was so aroused sexually that she could sleep only two or three hours a night. In order to relieve sex tension she masturbated frequently by massaging the region around the urethra.

"Since the patient has come to the city she has been very popular with men, has frequent dates and is widely known in her set. She goes out very often, dances a great deal and goes in for heavy petting with many men but has never allowed herself to have intercourse for fear of being discovered. The patient maintained that the penis and the two little glands in her groin were a nuisance and that she wanted them to be removed so that she could be a perfect woman. At the present time she is engaged to a man ten years older and he wants to marry her as soon as possible. She does not care to have any children, but she would like to have a normal sex life and, most of all, relief from sex tension through normal intercourse.

"The patient is an intelligent person with a masculine physique and appearance but is very feminine in her manner, so that one has the impression of a somewhat masculine girl. She shows an excellent appreciation of her problems, with good judgment, and her whole psychology seems to be entirely feminine, at least from the rather superficial contact with the examiner."

The foregoing examinations left little doubt as to the diagnosis of intersexuality. The presence of testicles implied the diagnosis of masculine pseudohermaphroditism. Since the patient had been brought up to be a woman, very much desired to be a woman and felt very unhappy about her masculine anatomic manifestations, we felt justified in performing a plastic operation to enlarge the rudimentary vagina and remove the penis and testicles. While complete restoration of masculinity in a case of intersex after removal of female organs has been reported,⁶ we did not hope a priori for restoration of female sex characteristics, because of the apparent absence of ovaries as determined by palpation and the x-ray appearance of the peritoneum. For that reason we concluded that laparotomy for diagnostic purposes was unjustified. The considerably increased excretion of gonadotropic substance furthermore seemed to indicate gonadal insufficiency and thus to exclude functioning ovaries. In that respect our case resembled the case of Novak,⁷ who found testicles intraperitoneally but no ovaries.

Operation (Dr. Rubovits).—Castration and amputation of the penis were easily accomplished by the simple technic employed for these operations. The rudimentary vagina was enlarged by invading the vesicorectal space up to the peritoneum. This area was then packed, with the hope that epithelization would occur. Daily digital and instrumental dilations were partly successful in maintaining a sexually serviceable vagina.

Microscopic Examination (Dr. Otto Saphir).—Sections of the soft globular masses stained with hematoxylin and eosin (fig. 3) revealed partially or completely hyalinized seminiferous tubuli showing no evidence of spermatogenesis. Scattered throughout or massed in the interstitial tissue were hypertrophic Leydig cells. Sections of the coiled peripheral structures revealed epididymis and vas deferens; of the columnar structure connective tissue containing endothelial lined spaces, smooth muscles and nerve fibers and tactile corpuscles, the whole simulating erectile tissue.

The patient made an uneventful recovery. While there were no striking changes in appearance as to masculine features, the breasts became fuller and somewhat enlarged. The patient expressed her gratification and is especially grateful for the

marked diminution of libido, which has made it possible for her to discontinue masturbation and resume her normal occupation.

COMMENT

It appears from the foregoing that we were dealing with a form of intersex which may be classified according to the older nomenclature as pseudohermaphroditism masculinus. Although a laparotomy was not performed and thus the absence of ovaries was not definitely established, this diagnosis would hold true even if some rudimentary ovaries were present, for the presence of both ovaries and testicles in one individual cannot be called true hermaphroditism unless there is definite evidence of gonadal function, such as the presence of both ova and spermatozoa. Our microscopic evidence of testicular tubular atrophy and absence of spermatogenesis is enough to rule out the diagnosis of

Fig. 3.—Section of testes showing atrophy of seminiferous tubuli and marked interstitial hypertrophy.

true hermaphroditism and to confirm again the fact that true hermaphroditism never has been found in man.

Our case offers several facts of interest. There is the psychosexual aspect. Here is a patient with masculine intersex, brought up to be a woman, suffering from intense libido toward the male sex and masturbation. The question arises whether sexual desire is a manifestation rather of environmental influences than of gonadal function. The fact that sexual tension was relieved by orchidectomy could be evaluated in favor of the assumption that the gonads are responsible for sexual desire even if expressed toward the same sex. The common embryonic origin of ovaries and testes, the near chemical relationship of androgenic and estrogenic substances, which are found excreted by both males and females, and the favorable effects of castration in homosexuality are factors that would interpret libido as a specific manifestation of gonadal activity, no matter

7. Novak, Emil: Sex Determination, Sex Differentiation and Intersexuality, with Report of Unusual Case, *J. A. M. A.* 105: 413 (Aug. 10) 1935.

toward which sex they are expressed and no matter as to the environmental influences.

Our case, furthermore, offers interesting features as to the problem of heterosexual manifestations. The marked hypertrichosis and hirsutism, the low voice and flat breasts and the virile pelvis doubtless are secondary sex stigmas due to the presence of male generative organs. Interstitial testicular function, which is considered responsible for the secondary sex characteristics, apparently was not disturbed in our patient in spite of the marked tubular atrophy and absence of spermatogenesis. This, in fact, is not surprising as ligation of the spermatic cord, which will produce testicular tubular atrophy and artificial azoospermia, is known to be followed by an increase of testicular interstitial activity both histologically and physiologically; interstitial hypertrophy, indeed, was very marked in our case, as evidenced histologically. We therefore may rightfully assume that the interstitial testicular function was not disturbed in our case.

How are physicians to consider those mild heterosexual symptoms in women encountered so frequently in everyday practice? There are apparently normal women with normal sex life who have borne several children and yet offer in varying degrees such virile features as hypertrichosis, male distribution of hair, male bony pelvis, flat atrophic breasts and deep voice. No satisfactory explanation can be given at present for that phenomenon. Recently Koch and his associates⁸ found that women with hypertrichosis and virilism were excreting considerably more androgenic substance than normal women. Such observations would point to an etiologic relationship between virilism in women and increased androgen production. The source of such production may theoretically be any derivative of the embryonic genital ridge, such as gonads or the adrenal cortex (interrenalism) either in situ or misplaced.⁹ It may well be conceivable that the presence of such aberrant or misplaced embryonic testicular tissue in women may give rise to a quantitative imbalance of gonadal hormone production and to the appearance of heterosexual symptoms.

Titration for gonadal factors has not yet been adequately undertaken in such cases. It seems, however, more than a coincidence that those manifestations known in the literature as adrenal virilism, Archard-Thier's syndrome, Cushing's syndrome and arrhenoblastoma ovarii always show involvement of either gonads or the adrenal cortex and always are characterized by marked heterosexual symptoms.

It is to be hoped that further studies of this kind may throw some light on the etiology of heretofore unrecognized mild forms of intersexuality in women.

SUMMARY AND CONCLUSION

1. Intersexuality is the anatomic manifestation of a disturbance in the mechanism responsible for the differentiation of the sex.

2. In a case of "female" intersex in which the patient had two testes and a small hypospadiac penis and secondary male sex characteristics, intense libido toward the male sex was relieved by orchidectomy.

Clinical Notes, Suggestions and New Instruments

RUPTURE OF THE GALLBLADDER WITHOUT ASSOCIATED CHOLECYSTITIS

HOWARD A. RUSK, M.D., AND ERNEST N. NEBER, M.D.
ST. LOUIS

Spontaneous rupture of the gallbladder complicating cholecystitis and cholelithiasis is relatively rare. A review of the literature fails to reveal a reported case of rupture without evidence of inflammation or stones. The diagnosis of this abdominal catastrophe is difficult because of the diversity of clinical symptoms, the lack of localization in the physical manifestations and the rarity of such a pathologic process.

The following report outlines the clinical and pathologic features of such a case:

REPORT OF CASE

A white man aged 58, an executive, seen March 23, 1937, complained at this time of failing vision, of four weeks' duration, and of nocturia (from two to three times). His past history

Fig. 1.—Gross specimen showing undersurface of liver, with ruptured gallbladder and large hematoma.

was of interest in that he had had a duodenal ulcer for a number of years, was operated on for adhesions in 1927, and had a gastroenterostomy in 1929 for a pyloric obstruction. He had been entirely relieved of his gastrointestinal symptoms following this operation. Aside from typhoid and diphtheria in his youth, the past history was not notable. His father and mother had both died at the age of 82 and there was no other history of cardiorenal disease in his family.

Physical examination showed a marked general and retinal arteriosclerosis with recent retinal hemorrhages. The heart was moderately enlarged to the right and left and the blood pressure was 212 systolic, 128 diastolic. An electrocardiogram showed a PR interval of 0.14 second with definite Q waves in

the chest lead and the T waves markedly inverted in lead 1, upright in leads 2 and 3 and inverted in the chest lead.

Laboratory examination at this time revealed white blood cells 6,000, red blood cells 4,000,000, hemoglobin 85 per cent, a blood smear slight anisocytosis and 12 per cent stab cells, non-protein nitrogen 40 mg., blood sugar 111 mg. per hundred

Fig. 2.—Section from wall of gallbladder at margin of necrotic area showing extensive hemorrhage and great thickening of medial coats of several arterioles with almost complete obliteration of the lumen. Reduced from a photomicrograph with a magnification of 200 diameters.

cubic centimeters, Kline reaction negative, intravenous phenol-sulfonphthalein 10 per cent in thirty minutes, the specific gravity by the Addis concentration test 1.014 at 7 a. m., 1.018 at 8 and 1.018 at 9, and a heavy precipitate of albumin in the urine, with no sugar, an occasional red blood cell and white blood cell and fine granular casts.

A diagnosis of hypertensive cardiovascular-renal disease was made, and the patient was put on a modified rest regimen with sedatives. His blood pressure during the next two months varied from 176/90 to 240/140.

September 17 the patient was hospitalized because of an increased blurring of vision, headaches, nocturnal dyspnea and attacks of syncope. At this time he showed a marked pitting edema of the lower extremities, moderate cyanosis and moist crepitant rales in both bases. The blood pressure on admission was 232/124. Laboratory tests at this time were not notable except for the nonprotein nitrogen, which was 54 mg. He remained in the hospital for eight days at this time, and on rest and digitalis the edema partially subsided but the other symptoms were unchanged.

He returned to his home and continued to be mildly decompensated, somewhat mentally confused and orthopneic. October 11 at 11 a. m., while having an elimination, he was seized with excruciating pain in the right upper quadrant associated with a small coffee ground vomitus. He was returned to the hospital in shock. On admission his blood pressure was 268/100, temperature 97.2 F., and respiratory rate 24. A very tender abdominal mass was palpable 6 cm. below the right costal margin but there was no abdominal rigidity. The blood count on admission showed white blood cells 6,200, of which 8 per cent were stab cells, 74 per cent segmented cells, 17 per cent lymphocytes and 1 per cent monocytes; red blood cells 3,560,000, with 67 per cent hemoglobin. Repeated white and red blood counts at intervals of two hours revealed no appreciable change from the original count. A tentative diagnosis of mesenteric thrombosis was made and the patient was given morphine and supportive treatment. The pain in the right upper quadrant remained so severe that it was difficult to keep him in bed. The mental confusion increased and partial restraint was necessary. His blood pressure varied from 268/100 to 175/85 and there was a progressive cardiac failure. He died forty-eight hours after admission to the hospital.

SUMMARY OF THE POSTMORTEM EXAMINATION (BY DR. L. S. N. WALSH)

Gross.—There was a large hematoma, which lay on the dorsal aspect of the liver. It originated in an opening in the

gallbladder wall which was about 1.5 cm. in diameter. The liver otherwise appeared normal.

The gallbladder was large, distended, purplish red and soft. The cystic duct contained blood.

Microscopic.—The liver appeared normal except that the periportal spaces were infiltrated by lymphocytes.

The pancreas appeared normal but the vessels in and around it presented advanced sclerotic changes, often with great thickening and hyalinization of the walls, which occluded them almost completely. This process was seen in small arterioles and seemed to involve both the media and the intima. A large vein appeared at several levels in which there was an organized and recanalized thrombus.

Sections from the gallbladder wall at some levels showed active vascular engorgement and hemorrhage into the tissue. Both well preserved and disintegrating erythrocytes with free pigment were seen. The filamentous processes of the mucosa at such levels were present and appeared normal except that they were forced widely apart. In the gallbladder wall small arterioles were encountered with greatly thickened and hyalinized walls, also arterioles with proliferation of the intimal coat practically occluding the vessel. The gallbladder wall near the site of rupture was loaded with extravasated blood and polymorphonuclear leukocytes. The mucous membrane had disappeared and many of the cells in the wall itself were necrotic.

The anatomic diagnoses were:

1. Hyperplastic arteriolar sclerosis involving the vessels of the pancreas, spleen, liver and kidneys with infarction, rupture and fatal hemorrhage from the gallbladder wall.
2. Arteriosclerosis, general.
3. Organized thrombophlebitis of the pancreatic vein.
4. Hypertrophy of the left ventricle.
5. Chronic diffuse nephritis (small, red, granular, arterio-sclerotic kidneys).
6. Hydropericardium.
7. Hemorrhagic erosions of the stomach.
8. Emaciation.
9. Appendectomy.
10. Gastroenterostomy.

Fig. 3.—Section of wall of gallbladder showing distention by hemorrhage with flattening and stretching of otherwise intact mucosa. Reduced from a photomicrograph with a magnification of 200 diameters.

11. Chronic visceral peritonitis, right upper quadrant.
12. Chronic periportal hepatitis.
13. Adenoma of the kidneys.
14. Chronic fibrous pleurisy.

COMMENT

A case of spontaneous rupture of the gallbladder occurred without associated cholecystitis. Although a pathologic rarity, this condition should be considered when making the differential diagnosis of an intra-abdominal catastrophe.

3720 Washington Avenue.

FRACTURES OF FEMUR—ENGEL AND MAY

TWO-PLANE DIRECTION AND RANGE FINDER FOR
NAILING FRACTURES OF THE NECK
OF THE FEMUR

GILSON COLBY ENGEL, M.D., AND HANS MAY, M.D.
PHILADELPHIA

JOUR. A. M. A.
MAY 28, 1938

DESCRIPTION OF INSTRUMENT

This instrument is composed of one plate instead of the two plates as originally described. This plate is a pie-shaped sector made of aluminum, which is faintly opaque to x-rays

Because of the extreme difficulty in getting the Kirschner wire in proper position to feed the Smith-Petersen nail on it, in nailing fractures of the neck of the femur and in determining the length of the femoral neck, our interest was stimulated to find a better method than that used today. It has been, and still is, easy to get the position of the fragments and the wire in good alinement in the one plane, anterior posterior, but the difficulty has been in getting these alinements in the

Fig. 1.—The instrument, its two fixing pins and the cap that screws on the ends of the fixing pins. The lines that converge toward the apex are opaque to x-rays, the rest of the plate only faintly so.

second plane, lateral, as well as the first. With the direction finder we feel that these difficulties are entirely eliminated, and besides being able to get perfect position regarding fragments, wire and nail, and the proper length of nail, it can be done through a small incision, which also is of advantage in elderly patients by making it possible for the patients to start motion at once and to get them out of bed early. Since our presentation of the first model,¹ further experimentation has brought the developmental stage of this instrument

Fig. 3.—The instrument held into the femur by its fixing pin, with the cap screwed snugly on the pin to hold the plate in place.

to the greatest point of simplicity and accuracy. The instrument we are presenting is the final outcome of experimentation and in this form has been given to the manufacturer for production. It can be used as a direction and range finder if the Smith-Petersen nail, the Henderson lag screw or the Moore nails are used for internal fixation of intracapsular fractures of the neck of the femur.

From the Lankenau Hospital, Philadelphia, service of Dr. George P. Müller.
Owing to lack of space, this article has been abbreviated in THE JOURNAL by the omission of some of the illustrations. The complete article appears in the authors' reprints.

Fig. 5.—Anterior posterior x-ray view showing the original fixing pin through the center line holding the plate in position, and the second pin inserted through the selected converging line, which passes through the center in the long axis of the neck of the femur.

Fig. 6.—This view shows the direction finder having been slipped off the square pin and refed on it at right angles to the original position. It is held by the cap screwed on the pin. The original fixing pin, of course, has been removed.

Fig. 7.—Method of taking the lateral x-ray plate. Note that the direction finder and the x-ray film are held parallel to each other, while the cone of the x-ray tube is perpendicular to these two plates.

(fig. 1). On this sector are converging lines of a metal which is densely opaque to x-rays, converging at the apex of the sector. Underlying each of these lines are two square canals, one canal being just under the other (fig. 2). In these canals

will fit square steel pins constructed with a tapering sharp point at one end and a screw thread tapped on the other. There is a cap which screws on the end of the pins. The purpose of this cap is, first, to take the blow of the hammer when the pin is driven into the cortex; secondly, to hold the plate snugly against the femur, and, thirdly, to withdraw the pin from the cortex of the femur by screwing up on the cap. All these canals take a $\frac{3}{32}$ -gauge Kirschner wire.

Fig. 11.—Anterior posterior view of the Smith-Petersen nail partially driven in on the Kirschner wire as a guide.

USE OF INSTRUMENT

The patient is anesthetized with spinal anesthesia and the fracture reduced by the Leadbetter maneuver. The leg is held by an assistant in abduction and about 10 degrees internal rotation. The skin over the affected thigh is prepared and an incision made from the great trochanter about 2 inches (5 cm.) in length, paralleling the shaft of the femur. This incision is carried down through the periosteum to the bone. The two-plane direction finder is then inserted into the incision so that the apex bisects the angle formed by the great trochanter and the shaft of the femur. The square pin is inserted into the center hole of the lower row of canals, the cap being partially screwed on, and is driven into the cortex of the bone. The plane of the direction finder is parallel to the long axis of the femur (fig. 3).

Fig. 13.—The method used to deduce the actual length of the femoral neck.

An anterior posterior roentgenogram is then taken and the converging line in the x-ray plate which is in the direction of the long axis of the neck of the femur is selected (fig. 4). Through the corresponding tube is inserted a second square pin in the opposite row of holes to which the first pin was inserted (fig. 5). The first pin is then removed by setting up on the thumb-screw cap, leaving only the second pin and the direction finder in position. The direction finder is then slid off of the second inserted pin, turned at right angles and inserted over the pin again, the pin passing through the center line of the upper row of canals. The screwcap is screwed snugly on this pin just to keep the plate in position (fig. 6).

A lateral x-ray view is then taken by pointing the cone of the x-ray tube under the unaffected leg, the thigh of this leg being flexed on the trunk, so that the cone of the x-ray tube is perpendicular to the plane of the direction finder and perpendicular to the x-ray plate, which is held parallel to the plane of the direction finder and just above it (fig. 7). From this lateral view we again select the converging line, which is in

the long axis of the neck of the femur in this view. Through its corresponding tube in the opposite row of holes to that in which the pin is fitted is inserted a Kirschner wire. This wire has previously been marked with a wire cutter (see deduction of measurements) so that when the mark on the wire reaches the outer edge of the direction finder we know that the point of the wire is just to the head (fig. 8). After the wire is in, the direction finder and its pin are both withdrawn (fig. 9). The Smith-Petersen nail is fitted over the wire and driven in with a nail impactor (figs. 10, 11 and 12). When it is home, the Kirschner wire is withdrawn and the fragments are impacted with the bone impactor. A few skin sutures are put in place and a small dressing is applied.

DEDUCTION OF MEASUREMENTS

Knowing the actual length of the direction finder, which is 9 cm., we find the actual length of the neck of the femur by a simple ratio. The actual length of the direction finder is to the length of the direction finder as measured on the anterior posterior x-ray plate as x (the actual length of the neck of the femur) is to the measured length of the neck of the femur in the x-ray plate. Thus we get the actual length of the neck of the femur to the actual length of the direction finder, we get the length, which we mark on the Kirschner wire. The actual length of the neck of the femur minus one-half inch, allowing for impaction of fragments, gives us the length of the nail to be used.

The operation is simple, accurate and nonshocking, making it possible to start motion at once; the patient is up in a wheelchair within forty-eight hours and on crutches within ten days to two weeks, depending on his physical strength.

RASMUSSEN ANEURYSM: ITS ROENTGEN APPEARANCE

REPORT OF CASE WITH NECROPSY

BARNET P. STIVELMAN, M.D.
Visiting Physician, Harlem and Riverside Hospitals

AND
MILTON MALEV, M.D., NEW YORK
Pathologist, Riverside Hospital

The existence of aneurysms of branches of the pulmonary artery in tuberculous cavities has been known for many years. In fact, they have long been recognized among the more common causes of massive and fatal hemoptysis in phthisis.

About 100 years ago, Fearn¹ gave what appears to be the first description of such an aneurysm. He reported the case of a man aged 41, "of spare and strumous habit," who suffered from a chronic cough, followed by fatal pulmonary hemorrhage. Postmortem examination revealed numerous cavities in both lungs and "in the upper left lobe there was an evacuated cavity, two inches in diameter and into it was seen jutting distinctly an aneurysmal sac as large as a nutmeg, which had burst by a cleftlike opening. The parietes of the sac were thin, and it did not contain any fibrinous layers. A vessel the size of a small crow-quill, leading from a considerable trunk of the pulmonary artery, was distinctly traceable into the sac."

A similar case was reported by Cotton² in 1861. His patient died after repeated hemoptyses, and an autopsy disclosed a cavity which contained an aneurysm as large as a walnut arising from "an artery about the size of a crow-quill running along its wall."

In 1868 Rasmussen³ reported a series of such aneurysms with a discussion of their pathologic appearance. These aneurysms have since been known by his name.

From the Tuberculosis Service of the Riverside Hospital, Dr. Max Taschman, director.

3. Rasmussen, F. W.: Hemoptysis Especially when Fatal in Its Anatomical and Clinical Aspects, *Edinburgh M. J.* 4: 385, 1868.

PATHOGENESIS OF RASMUSSEN ANEURYSM

The formation of these aneurysms has been variously explained. Rasmussen accepted Rokitsky's theory that they resulted from the absence of support on one side of the vessel following the destruction of the adjacent lung tissue. Furthermore, he maintained that the tendency for the vessel to expand toward the unsupported side was materially hastened by the increased intra-arterial pressure as a consequence of the

destruction of the neighboring blood vessels by the tuberculous process.

Aneurysms in young and rapidly growing cavities are, according to Jaffe,⁴ the result of disparity in the rate of occlusion of the vessel on the one hand and the rate of the progressing caseation on the other. He maintains that the vessel wall is weakened by the advancing caseous process at a time when it still has to carry the full load of blood pressure. Adventitia,

media and finally internal elastic membrane are destroyed by caseation necrosis, while the intima is slightly thickened. The necrotic portion of the wall is autolyzed by the pus in the cavity, and the thin remaining membrane is stretched and transformed into an aneurysmal sac.

FATE OF RASMUSSEN ANEURYSM

Unless death from rapidly progressive tuberculosis or its complications supervenes early, such aneurysms usually rupture at their apical aspect as a result of pressure against their weakened walls. Less commonly the rent occurs at their narrow stalk probably because of continuous pulsation and the weight of their contents. Rarely they "heal" by filling the entire cavity in which they are located. In such cases rupture is prevented by the support afforded by the walls of the cavity. In one of our cases the aneurysm turned into a solid mass of laminated clot and appeared to be in no way connected with the fatal issue.

While numerous reports and discussions of the Rasmussen aneurysms have appeared in the literature, little of value has been offered regarding their antemortem detection. It is our purpose in this communication to present a case, with post-mortem examination, in which the cavity and its enclosed aneurysm are clearly visible on the roentgenogram of the chest.

REPORT OF CASE

J. R., an American Negro laborer, aged 35, was admitted to the Riverside Hospital May 21, 1937. His family history and his previous history were irrelevant, except that he had an attack of pneumonia in the spring of 1935 and pleurisy in May 1936, from which he had apparently made a complete recovery. He began to cough and expectorate in January 1937 and soon experienced night sweats. He had a hemoptysis of about 100 cc. in April and it was because of progressive weakness that he sought admission to the hospital the next month.

On physical examination the patient was well nourished and well developed and showed no evidence of respiratory distress. There were dullness, bronchovesicular breathing over the upper half of the left lung and medium sized moist rales over the entire left side of the chest. His heart appeared to be normal. The blood pressure was 130 systolic and 82 diastolic. The urine was normal and the Kahn reaction of the blood was negative. The sputum was positive for tubercle bacilli (Gaffky VI).

Chest films (fig. 1) showed an advanced bilateral infiltration. In the lower portion of the left lung was a cavity about 4 cm.

in diameter, at the lower aspect of which was seen a dense irregular shadow, which, because of the recent hemoptysis, was thought to be due to a blood clot. The patient was kept at absolute rest. His general condition remained unchanged for two months. The temperature ranged between 99 and 100.6 F. The cough continued and the sputum amounted to about 100 cc. a day. He had a massive hemoptysis July 22, and the temperature rose to 104 F. Auscultation several days later showed moist rales throughout both lungs. Thereafter the patient's course was progressively downhill. His temperature fluctuated between 100 F. and 104 F. His cough became more and more violent and the sputum heavily streaked with blood. Several times the patient had small frank hemoptyses. He grew weaker and increasingly more dyspneic and died September 19, four months after his admission to the hospital.

AUTOPSY

Autopsy showed an extensive pulmonary tuberculosis, with cavitation at both apices. The air passages were free of blood. In the upper portion of the left lobe (fig. 2) about 4 cm. below the interlobar fissure and about 3 cm. in from the lateral margin of the lung there was a fairly fresh thin-walled cavity, with shaggy walls, containing a small amount of blood-stained debris. This cavity was two thirds filled by an intact, soft and apparently empty spherical gray mass which arose by a narrow stalk from the inner lower angle of the cavity. This stalk was ruptured on one side and could be easily traced through a small branch to a large trunk of the pulmonary artery. When the aneurysm was opened by an incision below its apex, it was seen to be empty above and to contain a loose blood clot below. The patient's repeated hemorrhages had apparently arisen from the small rent in the stalk, which had alternately closed and opened with the retraction of the blood clot.

COMMENT

Shadows of increased density within cavities have almost invariably been considered as due to unexpelled blood clots

following hemoptyses. No doubt this is true in the vast majority of cases, but in view of our observation it is well to bear in mind that such shadows may be due to aneurysmal dilatations of branches of the pulmonary artery. It seems reasonable to believe that a differential diagnosis between an aneurysmal dilatation and a blood clot within a cavity may be made roentgenographically. Dense shadows within cavities, if due to blood clots, will change in size, shape, contour and position and will disappear under observation. Shadows due to aneurysmal dilatations are more persistent and will not change rapidly in contour, size, shape and position, nor will they disappear on serial roentgenography.

The practical importance of recognizing these aneurysms is quite obvious. Experience has taught that it is best to collapse a bleeding tuberculous lung after the hemoptysis and blood spitting have ceased. In this way blood is not entrapped in the parenchyma and small bronchi, and a stormy course is avoided after the induction of pneumothorax. If this conservative procedure is followed in cases in which hemoptysis occurs because of a bleeding Rasmussen aneurysm, extensive bronchogenic spread or even exsanguination may occur. In

Fig. 1.—Advanced bilateral tuberculosis. The cavity in the left lower part of the chest contains a dense irregular mass.

Fig. 2.—Aneurysm within cavity in the left lower lobe.

4. Jaffe, R. H.: Pathology of Pulmonary Tuberculosis, in Goldberg's Clinical Tuberculosis, Philadelphia, F. A. Davis Company, 1935, p. 139.

such cases it would seem that the best interests of the patients would be served by early collapse in spite of the active hemoptysis and questionable condition of the opposite lung.

If the possibility of their existence and their roentgen appearance are kept in mind, Rasmussen aneurysms should be recognized more often before death than heretofore. The condition must be treated in the light of the fact that unless compressed effectively into the cavity in which the aneurysm rests, large and often fatal hemoptysis is the almost inevitable result.

25 Central Park West.

Special Article

VITAMIN E

H. A. MATTILL, PH.D.
IOWA CITY

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Some fifteen years ago several investigators in animal nutrition began to suspect that for normal reproduction the rat required a dietary constituent not yet recognized or included within the generally accepted group of accessories. At first there was some hesitation in accepting yet another member into the already large family of vitamins, but convincing evidence from various laboratories, especially from that of Evans and his co-workers, soon established the fact that when reared on diets otherwise complete, but not containing this new fat-soluble factor, rats did not have offspring, although they appeared to be quite normal in other respects. Male animals became infertile through degeneration of the germinal epithelium and the damage was irreparable. Females failed to carry their young to term; the embryos died and were absorbed, but the female reproductive mechanism as such was not damaged, since adequate dosages of the missing factor restored fertility. Still other experiments showed that diets in which this factor, although originally present, had been destroyed by oxidation were likewise inadequate for reproduction.

Thus vitamin E came into its own. In the five years that has elapsed since the publication of the previous symposium on vitamins in THE JOURNAL, our knowledge of vitamin E has been advanced considerably. It has been shown that at least three substances possess the effect of vitamin E, and their chemical nature is beginning to be understood. The need for vitamin E in other species, especially in domestic animals, its rôle in reproduction and possibly in other physiologic processes, its possible therapeutic value in preventing habitual abortion—these and other aspects have received active attention. Only the more significant papers can be discussed here; a summary of the earlier work and a bibliography prior to 1932 will be found in the previous review.¹

CHEMISTRY

A suitable starting point for a chronological presentation of the chemical status of vitamin E is its association

with antioxidants in nature. The antioxidants here concerned are substances which delay or prevent the auto-oxidation of fats and the rancidity resulting therefrom. The probable presence of these oxidation-inhibiting agents in certain vegetable oils, notably in wheat germ oil, which is rich in vitamin E, was deduced from the protection which this oil afforded against rancidity in certain experimental rations which were particularly susceptible to this form of oxidation. An actual association of antioxidant and vitamin E was first demonstrated in lettuce oil² and later in tomato and in wheat germ oil;³ subsequently other vegetable sources were also found to contain both.

The ready susceptibility of vitamin E to oxidative destruction under favorable conditions is the basis of the common practice to include cod liver oil, butter fat or lard, sometimes in incipient rancidity, in experimental rations designed to be deficient in E; there are many illustrations⁴ of the disappearance of vitamin E in the presence of these fats. Treatment of the food with ferric chloride⁵ has been employed for the same purpose, the explanation being that oxidation destroyed vitamin E or the protecting antioxidants, or both.

In order to examine the relations between vitamin E and antioxidants more carefully, Olcott and Mattill⁶ prepared a concentrate of vitamin E from wheat germ oil, which was found to have antioxygenic action as well as the biologic activity of vitamin E. This concentrate proved to be similar to the one first made by Evans and Burr some years ago and described in their monumental memoir on vitamin E. It differed in one respect from theirs: acetylation did not destroy the biologic activity although antioxygenic action was abolished. Hydrogenation was again found not to destroy the biologic activity (nor did it abolish the antioxygenic action) but the hydrogenation was incomplete even under very drastic treatment, as had been found by others.⁷ The destructive action of chlorine and bromine was reversible; boiling with zinc and hydrochloric acid in methanol restored biologic activity. Mild oxidation with silver nitrate seemed to reduce but not destroy vitamin E activity, but treatment with more vigorous oxidants such as potassium permanganate, ozone and perbenzoic acid did so.⁸

Of greatest chemical interest was the biologic activity of acetylated or benzoylated concentrates; the formation of such derivatives from vitamin E would signify the presence of one or more hydroxyl groups. The antioxygenic action, which in these substances probably depends on a hydroxyl group,⁹ was destroyed by such

Abstr.* **9**: 11407 (No. 6) 1935. Lassen, H. K.: The Influence of Butter Fat and Peanut Oil on the Growth and Fertility of Rats, *Acta path. et microbiol. Scandinav.* **11**: 183 (No. 2) 1934.

5. This was first suggested by Waddell and Steenbock and has been employed in some of the experiments to be reviewed here. According to M. W. Taylor and V. E. Nelson (Some Observations on Ferric Chloride Addition to the Diet, *Proc. Soc. Exper. Biol. & Med.* **27**: 764 [May] 1930), both the nature of the diet and the manner of applying the ferric chloride determine the result. The procedure destroys vitamin E, but the partial destruction of vitamin A, or of other unknown essentials, and the possible toxicity of the salt itself are all variables that often make the interpretation of results difficult.

esterification; biologic activity was not; hence, if vitamin E possessed a hydroxyl group, either it was resistant to esterification or the ester was physiologically utilizable. By an interesting series of reactions Olcott¹⁰ demonstrated that vitamin E does contain a hydroxyl group which is easily esterified and whose esters with acetic or benzoic acid are utilizable (hydrolyzable) by the animal body while a compound formed with phenyl isocyanate, for example, is not.

The presence of a hydroxyl group that could be acetylated was also demonstrated by Drummond and his co-workers¹¹ in comprehensive studies of the unsaponifiable fraction of wheat germ oil and of a very potent concentrate obtained from it. Only one of two oxygen atoms present could be acetylated, the other being inert, and the acetylated product was still active biologically. Reactions with iodine or hydrogen suggested the presence of three double bonds, but the concentrate resisted complete hydrogenation. Spectroscopic evidence, which is to be discussed, indicated that the hydroxyl group might be derived from a keto-enol structure but this view had to be abandoned later.¹² Data on surface pressures and surface potentials secured by Askew¹³ suggested a reduced polycyclic structure of the sterol type.

A study of the curves or bands in the absorption spectrum of the ultraviolet region is an increasingly useful tool for elucidating organic structure. This method was first applied to crude concentrates of vitamin E by Morton and Bowden and their co-workers.¹⁴ In the biologically active portion of much purer concentrates prepared from cottonseed as well as from wheat germ and palm oils Olcott¹⁵ found a band with a maximum at 2,940 angstrom units; this was later confirmed.¹⁶ His opinion that this band was not the property of the vitamin molecule but of some closely related impurity removable with difficulty, perhaps antioxidant,⁹ was based on the lack of parallelism between the intensity of this band and the vitamin E content as determined biologically. Some effective concentrates showed no band; others, notably from palm oil, produced an intense band but had low biologic activity. Furthermore, various reagents caused the band to migrate without seeming to affect the vitamin. Despite further careful work on this question, Drummond and his co-workers¹⁷ were compelled to leave it open.

Crystalline structure is usually considered a criterion of purity. All investigations thus far mentioned suffered from lack of purity of the starting material. This was a mixture; all the commonly used methods for isolating a substance in pure form had been unavailing. These included the use of varied solvents, high vacuum distillation which was often destructive, chromatographic absorption which Drummond found somewhat useful, and the preparation of crystallizable derivatives. Suc-

cessful application of the last method on a microchemical scale with cyanic acid to combine with the hydroxyl group finally enabled Evans and the Emersons¹⁸ to isolate three different crystalline allophanates from a vitamin E concentrate of wheat germ oil.¹⁹ When the alcohols were regenerated from them, one proved to be inactive biologically, another, later called β -tocopherol, had some activity, and the third, which they called α -tocopherol, was effective in doses of from 1 to 3 mg. It was a light yellow viscous oil which resisted all attempts at crystallization, but its conversion to another crystalline derivative (with *p*-nitrophenyl isocyanate), followed by reconversion to the allophanate and regeneration of the alcohol, left its biologic activity unimpaired. The peak of its absorption band was at 2,980 angstrom units, and micro-analysis indicated a provisional formula, $C_{29}H_{50}O_2$. Olcott, and especially Drummond, had been able to prepare concentrates having equal or even greater biologic activity than α -tocopherol. Is a mixture more effective than any of its separate constituents and what is pure vitamin E? Evans and his co-workers expressed the opinion that probably several closely related substances possess the biologic activity of vitamin E in varying degree. Soon thereafter they isolated the same α -tocopherol from cottonseed oil²⁰ and later²¹ still another active substance, γ -tocopherol, from the same source. Further intensive investigations revealed that only α -tocopherol is present in lettuce and that palm oil is qualitatively similar to cottonseed oil and like it contains no β -tocopherol. These substances have unequal biologic activity, the α being more effective than β - or γ -components. They also proved to be antioxygenic²² and hence possibly phenolic in nature, but the antioxygenic action did not parallel biologic activity, the γ being the most effective inhibitor. The confusion that has existed between the observations of different investigators is thus largely resolved, and the ultimate consequences of this resolution will be important. One may now speak of the multiple nature of vitamin E in much the same sense as we accept the fact that there are several substances which have vitamin D activity.

When the microtechnic of Emerson is applied on a larger (even if costly) scale,^{22a} sufficient material will become available for more comprehensive study of the vitamin E molecule(s). Indeed, some progress in this direction has already been made. By thermal decomposition of α -tocopherol Fernholz²³ produced a crystalline

sublimate which he identified as durohydroquinone (tetramethyl hydroquinone), and he suggested that α -tocopherol might be a mono-ether of durohydroquinone. The alkyl portion of the molecule is still under investigation. McArthur and Watson²⁴ have identified crystalline duroquinone in the selenium dehydrogenation products of α -tocopherol. They believe its origin to be in a sidechain consisting perhaps of two isoprene units. A fluorescent oily product, arising from the nucleus of α -tocopherol, is being investigated. Recently two new tocopherols from wheat germ oil have been described,^{24a} neotocopherol and cumotocopherol, the latter appearing to be a mono ether of pseudocumohydroquinone.

PHYSIOLOGY AND PATHOLOGY

The progress of the chemical studies which have been outlined required continuous animal assays of the biologic activity of the products obtained. The most suitable method of assay uses adult female rats, properly prepared by subsistence on a diet deficient in vitamin E. Ability to bear living young following the administration by mouth of varying amounts of concentrates is a measure of vitamin E potency; when the dose is inadequate the embryos die and are resorbed.²⁵ There is considerable and thus far uncontrollable variability in the response of individual animals to the same dosage, and few statistical studies have been reported.²⁶ The reason for this is obvious: until recently the concentrates were all mixtures, and investigators were primarily interested in knowing the minimum effective dose of their preparations.

The necessity of vitamin E for normal embryonic growth in animals other than the rat and the mouse has not been established, but several suggestive observations have been made in the field of animal production. The use of wheat germ oil or of natural foodstuffs has lessened the significance of the experiments as regards vitamin E itself. In the case of herbivorous animals, the very real difficulty of supplying a ration which is adequate in all respects save vitamin E has sometimes been met by treating the food with an ethereal solution of ferric chloride, thereby introducing still further complications.⁵ Such a ration has been found to support normal growth and reproduction in goats and rabbits for several generations.²⁷ Thus seven original goats increased to forty-eight in fifty-four months with no reproductive disorders attributable to avitaminosis E. Twelve original rabbits littered 137 young in two years; there were infrequent reproductive disorders the cause of which is not yet ascertained.

The carefully controlled veterinary studies on cattle have been continued by Vogt-Møller.²⁸ Intramuscular or preferably subcutaneous injection of 20 cc. of "Fertilan",²⁹ a sterilized wheat germ oil, into otherwise normal cows that have repeatedly failed to become pregnant was followed by pregnancy in thirty-three out of

fifty instances. Similar results were reported by Tutt.³⁰ Large doses of wheat germ oil increased the size of rabbit litters,³¹ wheat germ meal in the diet of sows reduced the mortality of suckling pigs,³² but this improvement may have been due to other constituents. The reported occurrence of vitamin E in the queen bee's royal jelly³³ could not be confirmed.³⁴

The results obtained with chickens are more conclusive and trustworthy because the vitamin E content of the food of the hens and of their eggs as determined by rat assay can be correlated with the hatchability of the eggs and the viability of the young chicks.³⁵ From such experiments it appears that vitamin E may be a limiting factor in the hatchability of eggs and that one manifestation of its deficiency is a first-week embryonic mortality. This is greatly reduced by supplying vitamin E in the poultry ration. Agricultural journals are beginning to carry advertisements recommending the use of feeds enriched with biologically tested wheat germ oil. If there is any justification for this, it arises in part in the increasing tendency to introduce concentrates and already compounded rations into animal feeding practice. A shortage of vitamin E might result from the consumption of a more or less limited diet, depending on the nature of the constituents. It is conceivable that on more natural forage, which would ordinarily supply enough E, an occasional animal might exhibit symptoms of a shortage through faulty absorption or metabolism.

The embryonic development of chicks in eggs from hens on a vitamin E deficient ration has shed some light on the abnormalities causing death in the embryo. According to Adamstone,³⁶ cell proliferation in the mesoderm produces a lethal ring in the blastoderm, whose blood vessels are choked off and disintegrate; the embryo dies from loss of blood and starvation. Observations on the degeneration in the testis of the male fowl³⁷ led him to conclude that vitamin E is intimately associated with the nucleus during cell division and probably exerts an indirect controlling influence.

Since the comprehensive morphologic studies made by Evans and Burr on the rat and described in their memoir, several workers have confirmed their observations. Thus Urner³⁸ found the embryo apparently normal until the tenth day, after which there was rarefaction of the mesenchyme and failure of the blood forming tissues. In the ectoplacenta also there was

failure of the mesodermal elements. According to others,³⁰ the malnutrition of the embryos is due at first to the imperfect phagocytic action of the trophoblast and later to imperfect development of allantoic blood vessels.

The striking difference in response to vitamin E deprivation by male and female animals can be explained, superficially, by the fact that in the male the damage is done to a part of the animal's own tissue and may for this reason be irreversible in contrast to the reparable damage in the female, which is wrought not on her own tissues but on those of the fetus. Among the nutritional factors concerned in testicular degeneration, vitamins A and E are probably the most important. On diets low in A and containing abundant E, degeneration appears earlier than under reversed conditions.⁴⁰ At first believed to be very similar,⁴¹ the histologic pictures presented by the two conditions are different, as demonstrated in a comprehensive study by Mason.⁴² Deficiency of vitamin E produces excessive liquefaction of the chromatin material, first in the spermatozoa and spermatids and later in the less mature cells; spermatogenic activity ceases soon after the first appearance of injury, whereas in vitamin A deficiency it continues in spite of considerable depletion of the germinal epithelium.⁴³ A careful survey of all the facts available leads Mason to the conclusion that vitamin E plays some very essential rôle in nuclear activities involving chromatin and is indispensable, especially in those tissues in which cellular proliferation and differentiation are unusually rapid. Such are the testis in the male and the developing embryo in the female.

A possible quantitative difference in the requirements of the two sexes⁴⁴ may emerge from this conception, the male requirement being greater than the female. This cannot be determined until larger amounts of the various tocopherols become available for study. Awaiting similar proof is the assumption of sex specific forms of vitamin E.⁴⁵

Does vitamin E have any other functions in the animal economy beyond those concerned with reproduction? Its effect in increasing the number and viability of the young⁴⁶ is a common observation; vitamin E is probably not concerned with lactation. Its favorable influence on extra-uterine growth, first observed by

Evans and by others,⁴⁷ was overlooked by some,⁴⁷ perhaps because their experiments were of too short duration. Interest was renewed in the subject by Blumberg⁴⁸ and by Ringsted.⁴⁹ The former demonstrated a retardation of growth in young rats at the twelfth to the fourteenth week (in males from the very beginning), complete cessation of growth at from eighteen to twenty-two weeks, and serious malnutrition and some muscular disturbance at from thirty to forty weeks when the animals were maintained on a highly purified ration deficient in vitamin E. Addition to the diet of wheat germ, the unsaponifiable fraction of its oil, or of natural foods known to contain E, produced a resumption of growth whereas allied substances known not to contain E had no effect. Ringsted's animals (females) reached a plateau of growth and first showed dragging of the hind limbs at 160 Gm. and at from 5 to 6 months of age; the paresis and malnutrition gradually increased on his synthetic diet, which contained lard previously aerated for ten hours at 110 C. and which was thus very rancid. Unfortunately he was unable to try curative procedures, but animals on the same diet that had received test doses of wheat germ oil adequate for successful reproduction remained free of paralysis.

Later work confirmed the growth promoting effect of vitamin E but without demonstrating any paralysis when this was withheld. Martin⁵⁰ exactly duplicated the basal diet and management that Blumberg used; the weights when growth ceased were slightly higher in both sexes, and the giving of a vitamin E concentrate restored growth. Attempts by various means to segregate a growth factor and a fertility factor in the concentrate led him to suggest that there were two agencies rather than a quantitative difference between the required amounts of a single substance. The total duration of his experiments is not indicated.

In a further study by Emerson and Evans,⁵¹ female rats on an E-deficient diet were surpassed by controls only after 4 to 5 months of age and at 250 Gm. in weight, and massive doses of wheat germ oil restored growth. At 19 months of age untreated animals had an unsteady gait but no paralysis. Olcott and Mattill⁵² also found no difference at 4 months between female animals on a synthetic E-deficient diet in which all the lipid constituents were of known composition, whether they were given a highly purified and tested concentrate of E or not. Male animals, on the other hand, were surpassed by controls from the age of 2 months; at 5 months the latter were 10 per cent heavier, but the former continued to grow and there was no paralysis. In both of these investigations an increased fat content (lard or ethyl esters of the fatty acids of edible fats) in the diet had a temporary stimulating effect on growth. Probably none of these studies were continued for a long enough time, for recently Burr and his co-workers⁵³ reported paralysis of the hind limbs in

22 months old female rats that had been on a highly purified E-deficient diet from weaning.

Equally mysterious is the paralysis in suckling rats from vitamin E-deficient mothers. First observed and studied by Evans, its incurable nature and its prevention by wheat germ oil and vitamin E concentrates have been confirmed repeatedly.⁵⁴ This condition was originally thought to be of nervous origin,⁵⁵ but it has now been definitely associated with skeletal muscles.⁵⁶ The muscles exhibit extensive degeneration and necrosis and their microscopic changes are not to be distinguished from those of muscular dystrophy in herbivora discussed later in this report; less extensive lesions may be present in the musculature of animals showing no external symptoms of paralysis or weakness.

The serious paralysis in first generation adult rats (Ringsted) was associated with a diet containing very rancid fat. The antioxygenic effect of the tocopherols and other inhibitors has up to now been considered as limited to the dietary mixture in which they are found and not as extending into the organism and its physiologic processes. Possibly the prolonged exposure of tissues to autoxidizing fatty acids and their products is as damaging to their chemically sensitive constituents as it is to the autoxidizable constituents of experimental diets. Support for this suggestion is found in the observations of Waddell and Steenbock⁵⁷ to the effect that on a ration treated with ferric chloride female rats were unable to use even large stores of vitamin E and did not acquire this ability until from four to six weeks after transfer to a nonoxidized basal ration. A further interesting item has recently come to notice;⁵⁸ subcutaneous injection (0.1 Gm.) of a concentrate prepared from rancid fat and containing aldehydes and ketones produced resorption of the embryos or failure of implantation^{58a} and fertility rapidly returned on discontinuance of the injections. Confirmation and interpretation of these observations will be significant for a proper understanding of the functions of vitamin E and its allied substances.

The relation of these various instances of paralysis to the muscular dystrophy first observed in herbivorous animals by Goettsch and Pappenheimer⁵⁹ is not clear. The latter type of dystrophy was first produced in guinea pigs and rabbits, even in utero,⁶⁰ on a diet deficient in vitamin E, but the addition of this to the diet did not prevent the development of the disease. On the same deficient diet, rats did not manifest the disease. According to Madsen, McCay and Maynard,⁶¹ cotton-

seed oil (containing a concentrate of vitamins A and D) in place of cod liver oil afforded a high degree of protection, and one of the causative factors resided in the saponifiable fraction of cod liver oil. Recently McCay, Paul and Maynard⁶² reported that the untoward effects produced by cod liver oil in the diet of herbivora were abolished when hydrogenated cod liver oil replaced the natural product. Muscle lesions in guinea pigs were entirely prevented by this substitution. Fats that easily become rancid are greatly stabilized by hydrogenation.⁶³

The experiments of Morgulis and Spencer⁶⁴ indicate that at least two factors are involved in this muscular degeneration; one of them is easily destroyed by treatment of the ration with ethereal ferric chloride. Both factors are present in fresh green alfalfa or in whole wheat germ; one of them is found in wheat germ oil, the other in lettuce or in dry alfalfa. The value of their metabolic and blood studies⁶⁵ is limited by the fact that inanition accompanies the dystrophy. The oxygen consumption of these degenerated muscles seems to be elevated,⁶⁶ but the metabolic rate of the afflicted animals is normal.⁶⁷

What value these observations may have for the understanding of human muscular dystrophy should be and is doubtless already a subject for careful inquiry. It must also be determined whether the resistance of rats is evidence of a qualitative or quantitative difference between them and the herbivora.

A functional relation between vitamins and internal secretions has been an intriguing if not very fruitful idea. Naturally, a possible connection of vitamin E with the sex hormones came to mind. It was Verzar⁶⁸ who first stated that vitamin E acted like anterior hypophyseal hormone in inducing precocious sexual maturity in young female rats but not in castrates and that E might be necessary for the formation of the hypophyseal hormone. Szarka⁶⁹ even concluded that E might be a building stone or precursor of the ovarian hormone, but since estrus is usually normal in vitamin E deficiency so direct a relationship is physiologically inadmissible. These views have found experimental contradiction in the work of many investigators;⁷⁰ vitamin E does not exhibit gonadotropic or luteinizing effects, nor do extracts of anterior pituitary, or pregnancy urine or

extracts of corpus luteum prevent reproductive failure in rats on vitamin E-deficient diets.

Although recently denied,⁷¹ there seems no doubt that, as first noted by van Wagenen,⁷² cellular changes take place in the anterior hypophysis of vitamin E-deficient male animals;⁷³ so-called castration cells appear, which are enlarged vacuolated basophile cells, but not of the signet ring type observed in surgical castrates. The condition is more marked in castrates than in vitamin E-deficient males; the glands of vitamin E-deficient female animals remain normal. E-deficient male pituitaries are more potent in the gonad-stimulating hormone than glands from normal animals and less potent than those of castrates, whereas E-deficient female glands do not differ from normal. This sex-different response in the pituitary would support the belief that the changes observed are directly the result of gonadal degeneration and are only indirectly concerned with vitamin E. The same significance probably attaches to the progressive hypertrophy of the mammary glands of vitamin E-deficient rats throughout a resorption gestation.⁷⁴

More recently however, biologic assay of pituitaries of E-free female rabbits by Rowlands and Singer⁷⁵ has given contrary results; such pituitaries demonstrated a decreased content of the luteinizing or ovulation-producing substance that is active in the rabbit, but such deficiency could not be considered a primary cause of the fetal resorption. The finding of hypoplastic thyroids in female E-deficient rats,⁷⁶ with return to normal appearance on administering E, suggests that thyrotropic as well as gonadotropic activity of the pituitary may be altered in the absence of vitamin E. Cretinism in young E-deficient rats has also been reported.⁷⁷

Interest in the possible relationship of vitamin E to malignancy was awakened by Davidson's observations on tar cancer in susceptible mice.⁷⁸ The incidence of such cancer was delayed and less frequent, and the animals remained in health longer, on an E-containing diet than on one deficient in it. Davidson acknowledged that the E-containing diet was better in other respects also, notably in vitamins B₁ and B₂. Earlier observations of Zagami⁷⁹ on the growth of grafts of Jensen sarcoma in rats demonstrated no significant differences as between animals with and without E in the diet. In the hands of Haddow and Russell,⁸⁰ liberal addition of wheat germ to the diet had no influence on the subsequent emergence of benzpyrene tumors, and unpublished work from this laboratory⁸¹ on the incidence and metastasis of methyl cholanthrene cancers in both ordinary and susceptible mice is to the same effect. On

the other hand, Adamstone⁸² found that the feeding of a ferric chloride treated diet to young chicks caused the development of characteristic visceral lesions, lymphoblastomas, with destruction of normal tissue and invasion by new cell growths. The uncertainty of the character of ferric chloride damage forbids any conclusions at this stage of study.⁸³ In this connection two unconfirmed reports should be mentioned; the healing of skin wounds in rats is hastened by a diet rich in E⁸⁴ or by external application of a concentrate.⁸⁵

THERAPY

Definite proof for the value of vitamin E as a remedy for sterility in human beings is manifestly difficult to secure. Many causes and conditions have been shown to be associated with human sterility, and, so far as animal experiments indicate, vitamin E is directly concerned with only one phase of the female reproductive process, namely, the blood supply and nutrition of the embryo, and in the male with the maintenance of testicular function. By analogy, an inadequacy of vitamin E in the human male might therefore be revealed either by nonviability or by complete absence of sperm; in the female by abortion, the physiologic counterpart of resorption in rats. Such analogies are unsafe as between animals of different species, for they may imply too much or too little.

Early observations¹ on the value of vitamin E in habitual abortion have been continued and amplified. Vogt-Møller⁸⁶ has reported two series of twenty and fifty-two cases in which no anatomic or physiologic abnormalities could explain repeated abortion. Administration of 3 Gm. daily of a purified wheat germ oil preparation resulted in the birth of living children in seventeen and thirty-eight cases, respectively. Watson and Tew⁸⁷ reported success in thirty-four of forty-six cases of previous abortion; wheat germ oil may also be useful as an adjunct in threatened abortion but is of no avail in the treatment of nonfertility from other causes. The success of Currie⁸⁸ seems to have been still more pronounced. By administering daily from the time of first attendance to the onset of labor a 3 minim (0.2 cc.) capsule containing a concentrate (Glaxo) from 5 Gm. of wheat germ oil, he secured twenty-three normal births out of twenty-four cases in which the aggregate seventy-three previous pregnancies had resulted in only 14 per cent of living children.

Massive doses of wheat germ oil have also, according to Shute,⁸⁹ been useful in abruptio placentae and have

83. Sufficient opportunity and time have not yet been afforded for verification of a striking announcement recently made by Rowntree and his co-workers (Rowntree, L. G.; Steinberg, A.; Dorrance, G. M., and Ciccone, E. F.: Sarcoma in Rats from the Ingestion of a Crude Wheat Germ Oil made by Ether Extraction, *Am. J. of Cancer* **31**: 359 [Nov.] 1937). When rats on an ordinary stock ration were fed a crude preparation of ether-extracted wheat germ oil, malignant tumors developed in the peritoneal cavity. They had the characteristics of spindle cell sarcoma and retained their malignancy through successive transplantations. Various preparations of refined wheat germ oil, extracted or expressed, and other vegetable and animal oils had no such effect. Whatever the agent may be, it is not vitamin E.

prevented progress of these cases to a severe stage of placental detachment. This clinical experience followed the observation⁹⁰ that the blood serum of aborting women had an increased resistance to tryptic proteolysis and that the serum of rats acquired the same property after about four months on a vitamin E-deficient diet; normal digestibility was restored in both cases by administering vitamin E. There is as yet no physiologic explanation for this.

More clinical evidence, obtained under carefully controlled conditions, is greatly needed to establish the usefulness of vitamin E therapy in abnormal human reproduction. Until this is at hand, attempts to produce a market for wheat germ oil among prospective parents generally are to be deprecated; so also is the suggested threat of national dietary sterility, in view of the widespread distribution of vitamin E in the foods belonging in a well balanced diet. Individual cases of inadequacy, due perhaps to faulty absorption or metabolism will not be understood until more is known about the chemistry and physiology of vitamin E.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SULFANILAMIDE (See New and Nonofficial Remedies, 1938, p. 450).

Sulfanilamide Tablets, 5 grains.

Prepared by Schieffelin & Co., New York, N. Y. No U. S. patent or trademark.

MANDELIC ACID (See New and Nonofficial Remedies, 1938, p. 292).

Mandelic Acid-Calco.—A brand of mandelic acid—N. N. R.

Manufactured by the Calco Chemical Company, Inc., Bound Brook, N. J. No U. S. patent or trademark.

SODIUM CACODYLATE (See New and Nonofficial Remedies, 1938, p. 102).

Hyposols Sodium Cacodylate, 3/4 grain (0.048 Gm.), 1 cc.

Prepared by The Drug Products Co., Long Island City, N. Y.

Hyposols Sodium Cacodylate, 1 1/2 grains (0.10 Gm.), 1 cc.

Prepared by The Drug Products Co., Long Island City, N. Y.

Hyposols Sodium Cacodylate, 3 grains (0.194 Gm.), 1 cc.

Prepared by The Drug Products Co., Long Island City, N. Y.

Hyposols Sodium Cacodylate, 5 grains (0.324 Gm.), 1 cc.

Prepared by The Drug Products Co., Long Island City, N. Y.

Hyposols Sodium Cacodylate, 7 1/2 grains (0.5 Gm.), 5 cc.

Prepared by The Drug Products Co., Long Island City, N. Y.

CEVITAMIC ACID (See New and Nonofficial Remedies, 1938, p. 480).

Cevitamic Acid-P. D. & Co.—A brand of cevitamic acid—N. N. R.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent or trademark.

Tablets Cevitamic Acid-P. D. & Co., 25 mg.

CHEPLIN'S EPINEPHRINE HYDROCHLORIDE SOLUTION (See New and Nonofficial Remedies, 1938, p. 232).

The following dosage forms have been accepted:

Cheplin's Epinephrine Hydrochloride Solution, 1:1,000, 10 cc.: marketed in rubber stoppered vials for parenteral administration.

Cheplin's Epinephrine Hydrochloride Solution, 1:1,000, 30 cc.: Marketed in rubber stoppered vials for parenteral administration and in screw cap vials for topical administration.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

CHOCALOSE

Manufacturer.—Borchardt Malt Extract Company, Chicago.

Description.—A chocolate flavored drink base containing powdered malt extract, chocolate, maltose, dextrose, bone calcium phosphate, and iron and ammonium citrate.

Manufacture.—The ingredients in formula proportions are mixed, resulting in a heavy liquid syrup. The mixture is dried to powder in vacuum driers and ground.

Analysis (submitted by manufacturer).—Moisture 3.1%, total solids 96.9%, ash 5.5%, fat (ether extract) 7.2%, protein ($N \times 6.25$) 8.3%, reducing sugars (as maltose) 66.3%, dextrose 9.5%, carbohydrates (by difference) 75.9%, caffeine 0.06%, theobromine 0.23%, calcium (Ca) 1.36%, phosphorus (P) 1.50%, iron (Fe) 0.094%, magnesium (Mg) 0.90%, potassium (K) 0.17%, sodium (Na) 0.01%, sulfur (S) 0.06%, copper a trace, manganese a trace, zinc a trace.

Calories.—4.0 per gram; 114 per ounce.

Vitamins.—74 International units of vitamin B₁ per ounce or 2.59 International units per gram.

PRUDENCE MACARONI WITH BEEF SAUCE

Manufacturer.—Boston Food Products Company, Boston.

Description.—Canned macaroni containing tomato purée, hydrolyzed wheat protein product, onion, beef, olive oil, cracker meal, vegetable shortening and seasoning.

Manufacture.—Ground onions and ground beef are sautéed in hot vegetable oil. The tomato purée, water and wheat protein product, which is used for flavoring purposes, are added and the mixture is boiled; the cracker meal and seasoning are then added and the mixture is boiled again. The cans are partly filled with the sauce and then the desired amount of cooked macaroni is added and lastly enough sauce is added to fill the cans. The cans are passed through rotary steam exhausters for five minutes at 180 F., sealed, heat processed and cooled.

Analysis (submitted by manufacturer).—Moisture 81.8%, total solids 18.2%, ash 1.2%, fat (ether extract) 2.0%, protein ($N \times 6.25$) 3.6%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 11.3%.

Calories.—0.8 per gram; 22.7 per ounce.

SUNNY DELL BRAND EVAPORATED MILK

Manufacturer.—Pevely Dairy Company, St. Louis.

Description.—Unsweetened, sterilized, evaporated milk.

Manufacture.—Milk from company inspected farms is tested, preheated, evaporated under vacuum, homogenized, cooled, standardized, filled into cans, sealed and sterilized.

Analysis (submitted by manufacturer).—Moisture 73.9%, total solids 26.1%, ash 1.3%, fat 7.9%, protein ($N \times 6.38$) 7.5%, lactose 8.9%.

Calories.—1.37 per gram; 40 per ounce.

MRS. PALEY'S BABY FOOD—STRAINED FRIJOLE BEANS

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, cooked, sieved frijole beans.

Manufacture.—Dried frijole beans are soaked, pressure cooked, sieved, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 77.0%, total solids 23.0%, ash 1.1%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 5.7%, crude fiber 1.0%, reducing sugars as dextrose 0.2%, sucrose 1.2%, total carbohydrate other than crude fiber (by difference) 15.0%, iron (Fe) 0.0013%, phosphorus (P) 0.090%, calcium (Ca) 0.042%.

Calories.—0.8 per gram; 22.7 per ounce.

SATURDAY, MAY 28, 1938

MISINFORMED SENATE PASSES BILL
FAVORING OSTEOPATHY

Senator Burke of Nebraska on Jan. 29, 1937, introduced a bill¹ to amend the United States Employees' Compensation Act so as to give osteopaths the same status under that act as is given to qualified physicians. On Feb. 11, 1937, Representative Drew of Philadelphia, himself an osteopath, introduced a bill² in the House of Representatives identical in its terms with Senator Burke's bill. These bills were referred respectively to the Senate and the House Committees on the Judiciary.

On behalf of the American Medical Association, protests were promptly filed and requests made that the American Medical Association be heard in opposition to such legislation. The situation was discussed editorially in THE JOURNAL, Feb. 20, 1937. Letters were written to secretaries of all state medical associations of states represented on the two congressional committees before which the bills were pending, suggesting that protests be filed with the two committees.

A subcommittee of the House Committee on the Judiciary gave a hearing on the bill, June 4, 1937, at which the American Medical Association was represented. The subcommittee later discussed with the Association amendments to the bill proposed by its osteopathic promoters. The subcommittee was informed that the amendments would not remove the opposition of the American Medical Association to the bill because that opposition was based on the unfitness of osteopaths generally to perform the duties that they would be liable to be called on to perform if the bill was enacted. Nevertheless, the bill was favorably reported by the committee, April 21, 1938. This situation was called to the attention of the medical profession by an editorial in THE JOURNAL, April 30, and to the attention of the several state medical associations by letter, with a view to eliciting protests by them. The bill, however, was reached on the Consent Calendar May 2, the ninth busi-

ness day after it was reported, and, there being no objection to its consideration, the bill as reported by the committee was passed without a voice being raised in opposition and with no debate whatever. The bill then went to the Senate and was there referred to the Committee on the Judiciary, in which its companion bill, introduced by Senator Burke, S. 1233, was pending. Notwithstanding the protest of the American Medical Association and protests that had been filed on behalf of state medical associations and without granting a hearing and even without referring the bill to a subcommittee for study and report, the Senate committee, May 9, ordered a favorable report on the bill.

When it was learned that the committee had taken that action on the basis of a statement made to it that the amendments inserted by the House of Representatives had removed all objection raised by the American Medical Association and others to the bill, a telegram was sent to Senator Ashurst of Arizona, chairman of the committee, informing him that the amendments had in no way diminished the opposition of the Association to the proposed legislation. His attention was called to the pending protest of the American Medical Association and its request for a hearing, and he was urged to take such action as might be necessary to give the Association an opportunity of showing why the proposed legislation should not be enacted. To this Senator Ashurst replied that the telegram would be laid before the Committee on the Judiciary for attention and consideration. Letters were promptly sent to state medical associations in the states represented on the committee and to certain other state medical associations calling their attention to the situation and urging their aid in defeating the proposal to place osteopaths throughout the country on the same basis as qualified physicians under the United States Employees' Compensation Act. The response by the state medical associations appealed to was general and vigorous.

Nevertheless, no action was taken to recommit the bill. It was called up in the Senate on May 18, at which time Senator King of Utah, without formally objecting to consideration of the bill, called attention to the fact that he had received a number of communications objecting to it and insisting on opportunities to be heard. To Senator King, Senator Burke made the following remarkable reply:

"The representatives of the medical societies suggested an amendment which has been put into the bill as it now stands. Those representatives, presumably speaking for all the national medical societies, have withdrawn their objection completely, and say that the bill is now all right."

Senator Burke reiterated later that the physicians stated they had no further objection to the bill, in view of the amendments that had been added by the House of Representatives. The bill was thereupon passed.

1. S. 1233, Seventy-Fifth Congress.
2. H. R. 4650, Seventy-Fifth Congress.

As far as the American Medical Association is informed, no physician authorized to speak or act for organized medicine took any part in framing the amendments that were added in the House of Representatives. These amendments, incidentally, are utterly misleading, for they do nothing more than provide that osteopaths in the several states shall limit themselves to osteopathic treatment as authorized by the laws of the states. Osteopaths would have been bound to observe such limitations without any such amendments.

The identity of "representatives, presumably speaking for all the national medical societies," on whom Senator Burke relied when he informed the Senate as to the representation is a mystery.

The whole incident gives rise to serious thought on the part of those familiar with the facts of the case as to the possibility of similarly misinformed actions in other cases.

ATMOSPHERIC CONTAMINATION

The study of air pollution in our large cities has been enormously stimulated. Every one is aware of the smoke pall which hangs over us; many are disturbed as to possible deleterious effects on our health. The investigations of the Mellon Institute of Industrial Research from 1911 to 1914 disclosed that the economic loss in the Pittsburgh area alone was \$10,000,000 annually. This cost was principally due to waste fuel, increased cleaning bills, ruined merchandise and corrosion of buildings. The problem is not, however, confined to cities of the United States. The recent study by Barrett¹ on atmospheric pollution in Toronto employed the methods developed by the committee for investigation of such fouling in Great Britain. Deposited impurity was measured at three locations within and at one location outside the city. Total solids deposited at the three locations within the city averaged 341, 358 and 610 tons per square mile annually, as compared with an annual deposit of 133 tons in the area outside the city. During the winter the average hourly suspended impurity was less than that found in London, England, but almost identical in amount with that found in the five cities of the United States showing maximum pollution. During the summer, in fact, more impurity was suspended in Toronto air than was found in the five United States cities. The comparison of the air on Sundays and week days showed the major part of Toronto's pollution to be of nonindustrial origin. Although, as Barrett points out, definite proof is lacking that smoke is significant from the standpoint of health, further studies may substantiate the alleged harmful effects. Even without such proof, however, purely economic and esthetic considerations should be sufficient to increase the control of the situation.

A report bearing on another phase of this problem has been published by Buchbinder and his collaborators.² This study was aimed at determining the number of alpha streptococci in the air in several types of locations in New York City. A total of 2,517 samples of air were examined by means of the Wells air centrifuge, sheep's blood agar cultures being used for determining the presence of alpha hemolytic streptococci. Forty-six per cent of the samples were from six schools, 20 per cent from the cars of a subway and 34 per cent from six theaters, six streets and a park. More streptococci were found in schools than in any of the other locations, as was evidenced both by the total number per cubic foot and by the percentage in positive samples. The subway, however, was a close second.

The streptococci found were studied from the point of view of their fermentation reactions, final p_H in dextrose broth, effect on litmus milk, and macroscopic and microscopic structure and effect on blood. The results indicated that although most properties of definite air streptococci agree well with those of common throat strains, several properties of the putative strains are at variance. The analysis of these similarities and divergences makes it seem justifiable, the authors believe, to assume that the aberrant forms are closely related to the streptococci of the throat and possibly derived from them. They concluded that streptococci of the alpha hemolytic type are widely distributed in the air, both in enclosed places of congregation and in the open spaces of a large city. A majority of the streptococci seem to be of nasopharyngeal origin. Many of them differ, however, in structure and in certain biochemical properties from typical alpha streptococci of the throat. It is suggested that these differences are due to the effects of aerial environment. There appears to be, finally, some association between the differences in streptococcus content of the air of enclosed places and the facilities for ventilation, though this point is somewhat difficult to correlate.

Such studies as these serve to corroborate the already well established fact that pollution of the air of our large cities is economically wasteful and hygienically undesirable. The factual information collected by these and similar investigations should not be allowed to go to waste by failure of municipal authorities to act. While further information on the exact effects of atmospheric pollution in the large cities on the health of the population is desirable and necessary, active attempts to improve the air both inside and outside buildings should not be delayed for further positive proof of injurious effects.

DISCLOSURE OF DRUG FORMULAS UNDER FEDERAL TRADE COMMISSION ACT

The Federal Trade Commission Act, as amended by the Wheeler-Lea Act of March 21, 1938,¹ forbids the dissemination of false advertisements to induce the sale of foods, drugs, diagnostic and therapeutic devices and cosmetics in interstate and foreign commerce and in commerce in the District of Columbia or in any territory. It provides, however, that—

No advertisement of a drug shall be deemed to be false if it is disseminated only to members of the medical profession, contains no false representation of a material fact, and includes, or is accompanied in each instance by truthful disclosure of, the formula showing quantitatively each ingredient of such drug.²

The only discoverable purpose of this provision of the act is to establish one rule of interpretation for the determination of the truth or falsity of advertisements of drugs when the advertisements are disseminated only to members of the medical profession and another rule for the interpretation of advertisements of drugs under all other circumstances, and of all foods, diagnostic and therapeutic devices and cosmetics. That this is the true purpose of the provision set forth seems clear from the rule laid down by the act for determining whether advertisements generally are or are not false. The act says:

In determining whether any advertisement is misleading, there shall be taken into account (among other things) not only representations made or suggested by statement, word, design, device, sound, or any combination thereof, but also the extent to which the advertisement fails to reveal facts material in the light of such representations or material with respect to consequences which may result from the use of the commodity to which the advertisement relates under the conditions prescribed in said advertisement, or under such conditions as are customary or usual.³

Apparently, the advertisements of drugs that are disseminated only among members of the medical profession are by the language of the act taken out of the general rule of interpretation of other advertisements. That rule makes the advertiser responsible not only for what he states in the advertisement but also for failure to reveal facts material in the light of his representations or material with respect to consequences which may result from the use of the commodity to which the advertisement relates under the conditions prescribed in the advertisement or under such conditions as are customary or usual. To bring an advertisement of a drug within the special rule of interpretation laid down for advertisements of drugs that are disseminated among the medical profession alone, it is necessary only that such material facts as the advertiser sees fit to state are not false and that the advertisement furnishes the physician with a truthful disclosure of the formula, showing quantitatively each ingredient of the drug. Nothing in the act, however, requires an advertiser of a drug

to protect himself by taking advantage of this special interpretation or to disclose his formulas. The omission of material facts by the advertiser of a drug to the medical profession, it will be noted, is not to be regarded as making the advertisement false within the meaning of the act, even though the facts omitted are material in the light of representations actually made or material with respect to the dangers inherent in the use of the drug advertised. Herein the rule of interpretation for the advertisement of drugs disseminated only to the medical profession differs from the rule of interpretation laid down for the advertisement of drugs under other circumstances and of all foods, devices and cosmetics.

The most that can be said for this provision of the act seems to be that if a published formula is to afford any protection whatever to the advertiser it must be truthful and must disclose the quantity of each ingredient of the drug advertised. Such disclosure does not seem to be limited to the disclosure of active or potent drugs, but excipients, solvents, flavors, colors and preservatives must be quantitatively disclosed along with the other ingredients. If there is to be any relaxation in this requirement it must come by administrative favor or judicial decision and not from the plain words of the act.

Current Comment

SELENIUM IN INDUSTRY

The primary purpose of a recent study of selenium reported by Dudley¹ is to point out those industries in which unrecognized hazards may exist as the result of the processing of selenium-bearing materials. He also describes the methods developed for the determination of selenium in the air as dust or vapor, and a satisfactory method of urine examination. That this study is by no means premature is evidenced by the increase in the domestic consumption of selenium from approximately 57,000 pounds in 1921 to 412,000 pounds in 1935. Selenium is now widely employed in industry and includes such processes as glass decolorization, plastics, rubber "accelerators," fire-proofing of electric cable, photoelectric apparatus, glass, paint and ink pigments and chemicals. The excretion of selenium in the urine is considered conclusive evidence that workers are absorbing selenium, but more clinical and experimental laboratory work is necessary to establish a differential diagnosis based on the quantity of selenium excreted. Dudley discusses a modification of the previously reported technic of urine examination for selenium so that amounts as low as 0.01 mg. can be determined. Only by an environmental survey, he states, with sampling of workroom atmosphere for selenium contamination, can there be any authentic evaluation of the occupational hazards inherent in any of the industries or processes. Such methods of

2. Public No. 447, Seventy-Fifth Congress, section 4.

3. Public No. 447, Seventy-Fifth Congress, section 4.

1. Dudley, H. C.: Selenium as a Potential Industrial Hazard, Pub. Health Rep. 53: 281 (Feb. 25) 1938.

analysis have been developed so that minute amounts of selenium may be determined in nearly any form or combination. The method consists of a sampling arrangement for absorbing gases or vapors with the ultimate recovery of selenium from a soda lime tube by distillation with hydrobromic acid. The selenium is precipitated and weighed or estimated colorimetrically. The extent of hazard in industries utilizing selenium is related primarily to the type of process. Fumes, vapors or liquids may result in definite dangers by the absorption of organic selenium compounds. Although skin absorption has not been studied experimentally, it has been shown that burns from hot acids containing selenium as the bromide result in the appearance of selenium in the urine within two days. An important corollary is that the normal human urine contains no distinguishable quantities of selenium. These considerations, Dudley believes, clearly show that selenium presents a potential industrial hazard and that adoption of control measures would be advisable in order to protect workers from injury resulting from absorption of seleniferous compounds.

THE SELECTION OF INTERNS FOR MUNICIPAL HOSPITALS

When it was proposed recently that interns for the New York City hospitals be selected by the Municipal Civil Service Commission and that the internship as a classified civil service position should carry with it a salary of approximately \$100 per month, the suggestions failed to receive the endorsement of Dr. S. S. Goldwater, Commissioner of Hospitals. The proposals were, moreover, vigorously opposed by the medical schools and private hospitals of the city. Now the New York Academy of Medicine makes available the report of a special subcommittee which has investigated this matter. The committee recommends that the rules governing the selection of interns should be uniform for all municipal hospitals except the university services; that all applicants for internships in the municipal hospitals be required to write a single examination, the identity of the candidates being unknown to the examiners who grade the papers; that medical school records and letters of recommendation be also considered, and finally that those candidates who have passed the preliminary written examination should be eligible for an oral and practical test which should be held at each hospital. The committee further recommends that the final selection of interns rest wholly in the hands of the medical boards of the several hospitals, 30 per cent being allowed for scholastic standing and character record, 30 per cent for the written examination and 40 per cent for the oral and practical examination. The situation in New York City is not unique, for similar proposals have been made in other large cities. The recommendations of the special committee of the New York Academy of Medicine offer a practical solution which deserves the consideration of the medical profession in all communities where similar problems arise.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

State Medical Election.—Dr. Seale Harris Sr., Birmingham, was elected president of the Medical Association of the State of Alabama at its annual meeting in Mobile April 21, succeeding Dr. Edward S. Sledge, Mobile. Dr. Roscoe C. Stewart, Sylacauga, was chosen vice president for the North-eastern division and Dr. Douglas L. Cannon, Montgomery, was reelected secretary. Montgomery was designated as the place for the next meeting, April 18-20, 1939.

ARKANSAS

Course in Pediatrics.—Lectures and clinics constitute a graduate course in pediatrics now being given throughout the state under the auspices of the Children's Bureau, U. S. Department of Labor, the Arkansas Medical Society and the Arkansas State Board of Health. Dr. Jean Valjean Cooke, associate professor of pediatrics, Washington University School of Medicine, St. Louis, the lecturer, opened the weekly sessions in Texarkana May 16, Camden May 16, Pine Bluff May 17, Forrest City May 18, Conway May 19 and Fort Smith May 20. Six meetings will be held in each series.

CALIFORNIA

Society News.—The Alameda County Medical Association, Oakland, was addressed April 18 by Drs. Leonard B. Barnard on "Newer Concepts in the Treatment of Osteomyelitis"; Oscar O. T. McAllister, "Manchester Operation for Uterine Prolapse"; Paul C. Samson, "Muscle Graft in Coronary Sclerosis," and Harry N. Akesson, "Gastroscopy as a Diagnostic Procedure."

Graduate Conferences.—A series of graduate conferences were recently held in Southern California under the auspices of the California Medical Association. One day sessions were held for the Riverside, Orange, Imperial and San Bernardino county medical societies, while a two day program was offered before the Santa Barbara County Medical Society. At the meeting of the San Bernardino society April 7 the following spoke:

Dr. Robert W. Langley, Los Angeles, The Decompensated Heart.
Dr. Robert W. Wilcox, Long Beach, Traumatic Surgery.
Dr. Frank W. Otto, Los Angeles, Colitis.
Dr. Orville N. Meland, Los Angeles, Malignancy.

GEORGIA

University Clinic Week.—Emory University School of Medicine will open a four day clinical session at Grady Hospital, Atlanta, May 31-June 3. Emory Alumni Day will be observed June 4. In addition to the clinics, the following will speak, among others:

Dr. Joseph H. Boland, Management of Compound Fractures.
Dr. Russell H. Oppenheimer, Home and Office Treatment of Heart Failure.
Dr. Emmett D. Colvin, Chronic Nephritis as a Complication of Pregnancy.
Dr. Max Cutler, Chicago, Recent Trends in the Radiation Treatment of Cancer.
Dr. William Carter Smith, Intravenous Use of Aminophylline in the Treatment of Certain Types of Heart Diseases and Bronchial Asthma.
Dr. William A. Selman will be toastmaster at the annual banquet and Dr. Oscar L. Miller, Charlotte, N. C., the speaker.

ILLINOIS

Personal.—Dr. Brockway D. Roberts, Wayland, Iowa, has been appointed professor of hygiene and director of student health at Knox College, Galesburg. Dr. Roberts graduated at the University of Illinois College of Medicine, Chicago, in 1935.

State Medical Election.—Dr. James H. Hutton, Chicago, was chosen president-elect of the Illinois State Medical Society at its annual meeting in Springfield May 19 and Dr. Samuel E. Munson, Springfield, was inducted into the presidency. Drs. Harry Otten, Springfield, and Clarence A. Earle, Des Plaines, were elected vice presidents and Drs. A. J. Markley, Garden Prairie, and Harold M. Camp, Monmouth, were reelected treasurer and secretary respectively.

Society News.—The Stephenson County Medical Society was addressed April 21 by Dr. John W. Ferrin, Chicago, on surgery of the prostate.—The Rock Island County Medical Society was addressed in Moline April 12 by Drs. Channing W. Barrett, Chicago, on "Preservation and Restoration of the Pelvic Floor" and Dr. George D. Hauberg, Moline, "Management of the Diabetic Patient."—The St. Clair County Medical Society was addressed in East St. Louis May 5 by Dr. William J. Dieckmann, Chicago, on "Abnormal Labor."—At a meeting of the Madison County Medical Society May 6 in Madison, Dr. Robinson Bosworth, East St. Louis, discussed "The Findings of Minimal Tuberculosis."—Dr. William R. Cubbins, Chicago, discussed "Fractures of the Hip" before the Sangamon County Medical Society in Springfield May 5.

Chicago

Appointments at University of Chicago.—Wilton M. Krogman, Ph.D., associate professor of physical anthropology and anatomy, Western Reserve University School of Medicine, Cleveland, has accepted a similar appointment at the University of Chicago, effective in September. According to the announcement Dr. Krogman will have the opportunity of developing a laboratory of physical anthropology at the university. A native of Oak Park, Ill., Dr. Krogman is secretary for the United States of the International Congress of Anthropology and Ethnology. He was field director of the archeological survey of Illinois for the University of Chicago during the summers of 1927 to 1930.—James Franck, Ph.D., since 1935 professor of physics at Johns Hopkins University, Baltimore, has been appointed professor of physical chemistry at the university, effective October 1. According to the *New York Times*, the appointment was made to focus fundamental studies of physical and chemical aspects of life processes basic to the study of disease, which the university has been conducting for some years. The primary objective of this cooperative research is to determine the normal processes of cell growth. Born in Hamburg fifty-five years ago, Dr. Franck received his degree of doctor of philosophy at the University of Berlin. He was awarded the Nobel prize in physics in 1925.

KANSAS

"Cancer Specialist" Enjoined from Practicing Medicine.—The Supreme Court of Kansas, May 7, found for the plaintiff in upholding the decision of the Wilson County trial court in the case of *State v. W. W. Cooper*, it is reported. This was an action in quo warranto brought to prevent Cooper, an unlicensed "cancer specialist" of Altoona, from practicing medicine and surgery in the state. In 1937, under an injunction law, passed through the efforts of the Kansas Medical Society, Cooper had been enjoined from practicing the healing art. He was said to be treating cancer, using a zinc chloride paste. A verdict in favor of the state was appealed by Cooper direct to the supreme court and the recent decision is the first of that court on the injunction law.

KENTUCKY

Health Units Consolidated.—The health units of Lexington and Fayette County have been consolidated into a single department under the direction of Dr. Charles D. Cawood, the present health officer of the county. Dr. Charles M. Moore recently resigned as city health officer.

Celebrations of Years of Practice.—Dr. James O. Carson, Bowling Green, entertained the Warren County Medical Society at a dinner recently, celebrating his completion of sixty years of medical practice. Dr. Carson is 82 years old.—Dr. John E. Wilson, Falmouth, celebrated the completion of fifty years of practice with a dinner, March 8, attended by physicians with whom he has been associated and other friends. Dr. Wilson was mayor of Falmouth for many years.

Society News.—Physicians of Woodford County recently met in Versailles and revived the Woodford County Medical Society, which had been inactive for several years. Dr. Charles F. Voigt, Midway, was elected president, and Dr. George H. Gregory, Versailles, secretary.—Louis A. Julianelle, Ph.D., St. Louis, addressed the Madison County Medical Society, Richmond, March 17, on "The Clinical and General Aspects of Inclusion Blepharitis."—Drs. Franklin Jelsma and Rettig A. Griswold, Louisville, addressed the Tri-County Medical Association in Lebanon March 31 on "Head Injuries" and "Treatment of Nonunited Fractures" respectively.—Dr. Thomas A. Griffith, Mount Vernon, addressed the Rockcastle County Medical Society, Mount Vernon, April 1 on pulmonary tuberculosis.—Dr. Emil Novak, Baltimore, addressed the Jefferson County Medical Society, Louisville, April 4, on

"Modern Conception of Organotherapy."—Dr. Baldwin H. E. W. Lucke, Philadelphia, addressed the Society of Physicians and Surgeons, Louisville, April 21, on "The Modern Concept of Bright's Disease."

MARYLAND

Conference on Mental Health.—At a conference on mental health at the Medical and Chirurgical Faculty Building, Baltimore, April 7-8, under the auspices of the Mental Hygiene Society of Maryland, the speakers included:

- Dr. Frederick H. Allen, director of the Child Guidance Clinic of Philadelphia, What Can I Do to Promote Better Mental Health of My Children?
- Burton Fowler, headmaster of Tower Hill School, Wilmington, Del., Means of Attaining Better Health for Students.
- Harrison S. Elliott, B. D., professor of practical theology, Union Theological Seminary, New York, What Can I Do to Promote the Better Mental Health of My Parishioners?
- Elton Mayo, M.A., professor of industrial research, Graduate School of Business Administration, Harvard University, Cambridge, Mass., How Can Employers Promote Better Mental Health for Their Employees?
- Miss Grace Marcus, case work consultant of the Charity Organization Society of New York City, Promotion of Better Health for Social Workers' Clients.

MASSACHUSETTS

Personal.—Russell L. Carpenter, Ph.D., assistant professor of anatomy, Columbia University College of Physicians and Surgeons, New York, has been appointed professor of zoology at Tufts College, Boston, succeeding Herbert V. Neal, Ph.D.—Dr. Raymond D. Tompkins, clinical director at the Veterans Administration Facility, Rutland Heights, has been appointed to a similar position at the facility in Mountain Home, Tenn.

Society News.—Dr. William B. Snow, New York, discussed induced fever as a therapeutic agent before the New England Society of Physical Medicine in Arlington Heights April 20.—The Worcester District Medical Society was addressed April 13 by Drs. David G. Ljungberg and Joel M. Melick, among others, on "Duodenal Diverticulum" and "Successful Termination of Pregnancy Following Double Sympathectomy" respectively.—W. Frank Walker, Dr. P.H., director of health studies, The Commonwealth Fund, New York, discussed "Changing Standards in Rural Health Work" before the Massachusetts Institute of Technology, Boston, April 15. This was the tenth Delta Omega Lecture.

MICHIGAN

Alumni Reunion.—The forty-ninth annual reunion and the Detroit Clinics of the Alumni Association of Wayne University College of Medicine will be held June 15-16. A program combining preclinical and clinical material has been arranged to cover the needs of the general practitioner and the specialist. Thursday will be given over to the commencement program of the school of medicine, a boat ride and the reunions of classes.

Personal.—Joel B. Peterson, Ph.D., formerly on the staff of the Chemical Laboratory of the American Medical Association, Chicago, was recently appointed director of chemical research with Frederic Stearns & Company, Detroit.—George P. Bugbee, assistant director, University of Michigan Hospitals, Ann Arbor, has been appointed administrator of the Cleveland City Hospital, effective June 15. He succeeds James A. Hamilton, who will become superintendent of the New Haven Hospital, New Haven, Conn.

Neuroanatomic Conference.—The laboratory of comparative neurology, University of Michigan Medical School, Ann Arbor, sponsored a neuroanatomic conference April 18. Visiting speakers on the program were Charles Judson Herrick, Sc.D., emeritus professor of neurology, University of Chicago, who spoke on "The Cortex in Relation to Learning"; Drs. Stephen W. Ranson, director, Institute of Neurology, Northwestern University Medical School, "Somnolence Caused by Hypothalamic Lesions in the Monkey," and Dr. Elisha S. Gurdjian, Detroit, "Certain Aspects of Spinal Fluid Pressure Changes."

Society News.—Dr. Albert C. Furstenberg, Ann Arbor, discussed "Clinical Significance of Acute Infections of the Mouth and Throat" before the Ingham County Medical Society in Lansing March 15.—Dr. Hugo A. Freund, Detroit, discussed "Diseases of the Peripheral Blood Vessels" before the Muskegon County Medical Society in Muskegon April 22.—Dr. Raymond B. Allen, dean, Wayne University College of Medicine, Detroit, was the toastmaster at the annual banquet of the Phi Beta Pi Medical Fraternity at the Fort Shelby Hotel, Detroit, April 30. Dr. Clarence E. Umphrey presented a paper entitled "Medicine Branches Out."—Dr. Robert C. Moehlig, Detroit, addressed the Jackson County Medical

Society, Jackson, March 15, on endocrine disturbances in general practice.—At a meeting of the Eaton County Medical Society in Charlotte, March 17, Dr. Willard Van Hazel, Chicago, spoke on "Empyema and Surgical Conditions of the Chest."—Dr. Charles Leslie Mitchell, Detroit, discussed "Low Back Pain" before the Calhoun County Medical Society, Battle Creek, May 3.

MISSOURI

Annual Clinical Conference.—The annual graduate course and clinical conference of the St. Louis Clinics was held May 23-28. Medical, dental and surgical subjects were considered. The material was not arranged into courses but the subject matter was selected with special reference to the requirements of the general practitioner. Members of the medical department officers of the U. S. Army and Navy cooperated in the conference, which was presented solely by St. Louis physicians.

Dr. Casey Goes to Louisiana.—Dr. Albert Casey, associate of pathology and chairman of the department, St. Louis University School of Medicine, St. Louis, has been appointed assistant professor in the department of pathology and bacteriology at Louisiana State University School of Medicine, New Orleans. Dr. Casey has served on the staff of the Rockefeller Institute for Medical Research and as associate professor of pathology at the University of Virginia Department of Medicine. Since 1936 he has been on the staff of St. Louis University, from which he graduated in 1927.

NEBRASKA

State Medical Election.—Dr. Arthur L. Miller, Kimball, was named president-elect of the Nebraska State Medical Association at its annual meeting in Lincoln April 28, and Dr. Homer Davis, Genoa, was installed as president. The next annual session will be held in Grand Island.

Society News.—A symposium on arthritis was presented at a meeting of the Lancaster County Medical Society, Lincoln, April 5 by Drs. Miles J. Breuer and Frederick F. Teal Jr.—Drs. R. L. Traynor and William H. Schmitz, Omaha, addressed the Madison Six County Medical Society in Norfolk April 19 on diseases of the pericardium, and prostatism.

Fifty Years of Practice.—The Richardson County Medical Society recently gave a dinner in honor of the sixtieth wedding anniversary of Dr. and Mrs. John A. Waggener, Humboldt. Dr. Waggener has practiced medicine for sixty-two years.—Drs. C. A. Bradley and Clifford P. Fall, Beatrice, recently received medals from the Gage County Medical Society in honor of their long years of practice. Dr. Bradley has practiced fifty-two years and Dr. Fall fifty years.

NEW YORK

Syracuse Alumni Reunion.—Alumni of the Syracuse University School of Medicine will hold their annual reunion June 6-7 at the school. The following program is announced for the scientific sessions:

- Dr. Russell L. Cecil, New York, Treatment of Pneumonia.
- Dr. Frank L. Jennings, Oak Terrace, Minn., Pneumothorax in the Treatment of Pulmonary Tuberculosis.
- Dr. John H. Stokes, Philadelphia, Treatment of Syphilis.
- Dr. Harold E. B. Fardee, New York, Treatment of Heart Disease During Pregnancy and Labor.
- Dr. John J. Corbett, Detroit, Rectal Fistula.
- Dr. Charles D. Squires, Binghamton, Diagnosis and Treatment of Acute Surgical Emergencies.

There will be an exhibit of physicians' hobbies and a dinner at the Hotel Onondaga.

New York City

Diabetes Association Incorporated.—Announcement was made May 1 of the incorporation of the New York Diabetes Association. Formerly an affiliate of the New York Tuberculosis and Health Association, the new corporation has separate offices at 22 East Fortieth Street. This action is said to mark the opening of a renewed campaign to aid 75,000 diabetic patients in the city; 2,500 persons died from diabetes in the city last year.

Report of the Hospital Commissioner.—Dr. Sigismund S. Goldwater, commissioner of hospitals, transmitted to the mayor April 28 the annual report on thirty institutions under his jurisdiction. In 1937 the city cared for 266,682 patients in the city hospitals and paid for the care of an additional 103,000 in private hospitals and homes for the aged and infirm. The hospitals are staffed by 4,406 visiting physicians who gave their time and by 1,669 paid physicians, half of whom were

interns in training. In addition there were 7,844 nurses and attendants. There were more than 43,000 major operations performed, and 16,306 babies were born in the hospitals. Total expenditures of the department were \$24,331,374. The average daily per capita cost for hospitalized patients was \$3.58, for outpatients 37 cents. Both are larger than the figures for the previous year because of improved service, the eight hour day and increased cost of commodities, the report said. Sums collected from city patients amounted to \$844,247, contributions to \$623,877.

Society News.—Speakers at the stated meeting of the New York Academy of Medicine recently were Drs. Edwards A. Park, Baltimore, on "Recognition of Deficiencies in the First Four Vitamins and Measures for Prevention"; John G. Fitzgerald, Toronto, "Specific Prevention of Diphtheria—Further Observations and Inquiries," and James P. Leake, U. S. Public Health Service, Washington, D. C., "Variations in Incidence in Infectious Diseases." At this meeting the academy's gold medal was presented to Dr. Bela Schick (THE JOURNAL, March 19, p. 906).—Drs. Bernard Seligman and George B. Dorff addressed the New York Endocrinological Society March 23 on "Hirsutism: Etiology and Treatment" and "Observations on Treatment of Intra-Abdominal Cryptorchidism with Anterior Pituitary-like Hormones" respectively.—Drs. Henry H. Kessler, Newark, N. J., and Joseph J. Eller, among others, addressed the Society of Plastic and Reconstructive Surgery March 24 on "Cineplastic Surgery and Prosthesis" and "Cosmetic Results in the Treatment of Skin Tumors" respectively.—The class of 1898 of Bellevue Hospital Medical College held its fortieth anniversary dinner at the Hotel Croydon May 26.

OHIO

Dr. Pickering Lectures.—Dr. George W. Pickering, assistant in the department of clinical research and lecturer in cardiovascular pathology, University College Hospital, London, England, gave the Frank E. Bunts Lecture at the Cleveland Clinic May 5 on "The Problem of Human Hypertension." Dr. Pickering also delivered the forty-third Hanna lecture at Western Reserve University School of Medicine May 6 on "Experimental Studies on Headache."

PENNSYLVANIA

District and County Society Meeting.—The annual meeting of the Tenth Councilor District Medical Society (Allegheny, Beaver, Lawrence, Westmoreland counties), May 12, was in conjunction with the annual graduate program of the Beaver County Medical Society in Beaver Falls. The survey of the American Medical Association on local medical service needs was the theme of the district society. The scientific program included the following speakers:

- Dr. George J. Kastlin, Pittsburgh, Hodgkin's Disease.
- Dr. William H. Guy, Pittsburgh, Management of Malignant Glands of the Neck.
- Dr. Russell B. Bailey, Wheeling, W. Va., Collapse Therapy.
- Dr. Arthur J. Skeel, Cleveland, Uterine Hemorrhage.
- Dr. Walter C. Alvarez, Rochester, Minn., Hints in Gastrointestinal Disorders.
- Dr. William Wayne Babcock, Philadelphia, Practical Points in General and Minor Surgery.

Dr. Thomas Parran, Washington, D. C., surgeon general, U. S. Public Health Service, addressed the afternoon public meeting on "Syphilis Can Be Stamped Out." He, with Dr. Alvarez, and Drs. Frederick J. Bishop, Scranton, and David W. Thomas, Lock Haven, president and president-elect, respectively, state medical society, addressed the banquet in the evening.

Philadelphia

Medical College News.—Dr. Anton J. Carlson, Chicago, delivered the annual Alpha Omega Alpha Lecture of the Woman's Medical College of Pennsylvania March 29 on "Government Medicine and Public Health." Dr. Arvid Lindau, professor of general pathology and bacteriology at the University of Lund, Sweden, lectured at the college March 28 on "Pathogenesis of Peptic Ulcer."

Society News.—The Philadelphia County Medical Society held a special meeting May 3 in observance of National Child Health Week, with a symposium on "The Family Doctor and the Child." The speakers were Drs. William C. Hunsicker, director of public health; Ralph M. Tyson, John F. Sinclair, John P. Scott and James J. Waygood.—At a meeting of the Medical League April 25 the speakers were Drs. Ernest A. Spiegel on "The Mechanism of Pain"; John F. Huber, "Anatomical Factors in Palpation of the Dorsalis Pedis Artery" and Hugh Montgomery, "Peripheral Vascular Dis-

case."—The annual meeting of the Philadelphia Heart Association was held April 27 with Dr. Robert L. Levy, New York, as the guest speaker on "The Diagnosis of Cardiac Diseases"; Dr. David Riesman reviewed the society's activities during the year.—Dr. Russell M. Wilder, Rochester, Minn., delivered the forty-first Mary Scott Newbold Lecture of the College of Physicians of Philadelphia May 5 on "Recent Clinical and Experimental Observations in Adrenal Insufficiency."

Pittsburgh

Dr. Whipple Gives Mellon Lecture.—Dr. George H. Whipple, dean and professor of pathology of the University of Rochester School of Medicine, Rochester, N. Y., delivered the twenty-first Mellon Lecture of the Society for Biological Research at University of Pittsburgh School of Medicine, May 18. He discussed "Protein Production and Exchange in the Body, Including Hemoglobin, Plasma Protein and Cell Protein."

TENNESSEE

Graduate Course and Military Symposium.—A two day graduate clinical conference offered in conjunction with a medical military symposium will be conducted at Vanderbilt University School of Medicine, Nashville, June 6-7. Reserve officers will receive "inactive duty" credit for attendance. Dr. and Mrs. G. Canby Robinson, Baltimore, will be guests of honor at a dinner concluding the sessions. Dr. Robinson was formerly dean of Vanderbilt.

VERMONT

Personal.—Dr. Charles S. Woodall, formerly assistant superintendent of the Walter E. Fernald State School, Waverley, Mass., has been appointed superintendent of the Brandon State School for the feeble-minded at Brandon.

Millions Willed to Bennington Hospital.—The Henry W. Putnam Memorial Hospital, Bennington, is to receive \$3,000,000 by the will of late Henry W. Putnam, New York wire and glass manufacturer, who died March 30. The hospital was founded by Mr. Putnam's father in 1912.

WISCONSIN

Executive Secretary Appointed.—Mr. James O. Kelly, Milwaukee, has been appointed executive secretary of the Medical Society of Milwaukee County, succeeding Mr. Theodore Wiprud, who has accepted a similar position with the Medical Society of the District of Columbia, Washington. During the last several years, Mr. Kelly has assisted the State Medical Society of Wisconsin on such projects as graduate clinics on infant and maternal welfare, district meetings and the annual meetings of the society. In 1936 he was appointed by the governor to conduct a survey of hospitals and physicians in Wisconsin to secure accurate information on the problems of hospitals and physicians in connection with automobile accidents. He is the son of Dr. and Mrs. Francis H. Kelly of Merrill.

Graduate Medical Education Programs.—Two types of graduate education programs are being offered throughout the state during May and June under the auspices of the council on scientific work and the committee on maternal and child welfare of the state medical society and the bureau of maternal and child health of the state board of health. A one day program, consisting of an afternoon and evening meeting, is scheduled for Stevens Point, Wausau, Marinette, Sheboygan, West Bend, Manitowoc, Wisconsin Dells, Fond du Lac, Waukesha and Racine. Dr. Paul Padget, Baltimore, will discuss syphilis, and another speaker, whose name is not given, will talk on obstetrics. In the afternoon Dr. Padget will be available to the county medical societies in the areas served for clinics. The bureau of maternal and child health will present courses on obstetrics and pediatrics in Baraboo Mondays, Richland Center Tuesdays, Viroqua Wednesdays, Lancaster Thursdays and Monroe Fridays. Lectures will be delivered one afternoon and evening each week for five weeks. The first two meetings will be devoted to prevention and treatment of toxemias of pregnancy, and infections and hemorrhages of pregnancy. The third session will deal with prematurity from both the obstetric and the pediatric aspect, while the fourth and fifth sessions will be devoted to pediatrics and will encompass the following topics: meningitis, acute and chronic abdominal conditions, the complications of respiratory infections, internal secretions in childhood, drugs commonly used in pediatric practice and pyuria.

GENERAL

Alumni Meeting.—The alumni of the University of Louisville will hold a banquet at the Clift Hotel, San Francisco, Wednesday evening June 15. Dr. R. C. Arnold, U. S. Marine Hospital, San Francisco, is in charge of reservations.

Courses for Teachers of Sight-Saving Classes.—The National Society for the Prevention of Blindness announces that courses for the training of teachers and supervisors of sight-saving classes will be offered at the summer sessions of the following institutions:

Tulane University, New Orleans, June 13 to July 23.
University of Cincinnati, June 20 to July 26.
University of Hawaii, Honolulu, June 27 to August 5.
Seattle, June 20 to July 20.
June 27 to August 5.
Buffalo, July 5 to August 12.
University, New York, July 6 to August 13.

Association for Research in Ophthalmology.—The annual meeting of the Association for Research in Ophthalmology will be held in San Francisco Tuesday June 14 at the Mark Hopkins Hotel. Among the speakers will be:

Drs. James H. Allen and Alson E. Braley, Iowa City, Experimental Studies of the Pathogenicity of Staphylococcus Toxin.
Dr. Hermann M. Burian, Hanover, N. H., Influence of the Central Nervous System on the Pigment Migration in the Retina of the Frog.
Drs. Conrad Berens, Daniel Murray Angevine, Loren P. Guy and Sidney Rothbard, New York, Eye Lesions in Experimental Lesions, with Special Reference to Arthritis.
Drs. William E. Borley and Maurice L. Tainter, San Francisco, Influence of Dinitrophenol on the Production of Experimental Cataracts by Lactose.

American Proctologic Society.—The thirty-ninth annual meeting of the American Proctologic Society will be held at the St. Francis Hotel, San Francisco, June 11-13, under the presidency of Dr. Harry Z. Hirshman, Philadelphia. Among the speakers will be:

Dr. Montague S. Woolf, San Francisco, Curability of Chronic Ulcerative Colitis.
Dr. Marion C. Pruitt, Atlanta, Ga., Questionable Proctologic Problems.
Dr. Newton D. Smith, Rochester, Minn., Perianal Pyoderma.
Dr. Martin S. Kleckner, Allentown, Pa., Importance of Low Spinal Anesthesia in Proctologic Operations.

A group of papers on prolapse will be presented by Drs. Rufus C. Alley, Lexington, Ky., Mark L. Emerson, Oakland, and Alfred John Murieta, Los Angeles, Calif.

Meeting of Ophthalmologists.—The seventy-fourth annual meeting of the American Ophthalmological Society will be held at the Mark Hopkins Hotel, San Francisco, June 9-11. The following, among others, will present papers:

Dr. William H. Crisp, Denver, Shall We Use Cycloplegics?
Dr. Edward Jackson, Denver, Subjective Study of Visual Aberrations.
Dr. Charles W. Tooker, St. Louis, Metastatic Septic Endophthalmitis with Ring Abscess of the Cornea—Case Report and Pathological Anatomy.
Dr. Edwin M. Neher, Salt Lake City, A New Method for Transplanting Pterygium.
Dr. Arthur J. Bedell, Albany, N. Y., Traumatic Retinal Angiopathy.
Dr. Frederick T. Tooke, Montreal, Canada, A Case of Aleukemic Lymphosis Involving the Upper Lids, with Pathological Findings.
Dr. Trygve Gundersen, Boston, Results of Autotransplantation of Cornea Into the Anterior Chamber: Their Significance Regarding Corneal Nutrition.

Association for Study of Allergy.—The sixteenth annual meeting of the Association for the Study of Allergy will be held at the Hotel Empire, San Francisco, June 10-11. Among the speakers will be:

Dr. Orville H. Brown, Phoenix, Ariz., Practical Bacterial Vaccines for Each Case.
Drs. Robert W. Lamson, Los Angeles, and Harry L. Huber, Chicago, Long Continued Hypodermic Use of Large Amounts of Epinephrine.
Dr. Norman W. Clein, Seattle, Allergy in Infants: The First Allergic Manifestations.
Dr. Orval R. Withers, Kansas City, Mo., Food Allergens: Atopic Reagents and the Botanical Classification of Foods.
Dr. Morris Murray Peshkin, New York, Sensitization to Tobacco in Allergic and Nonallergic Children with Passive Transfer Studies.

There will be a round table luncheon Saturday and the annual dinner will be held Saturday evening.

Meeting of Clinical Pathologists.—The seventeenth annual meeting and fifth seminar of the American Society of Clinical Pathologists will be held at the Palace Hotel, San Francisco, June 9-11. The following will speak among others:

Drs. Alfred S. Giordano, Agatha M. Wilhelm and Mildred C. Prestud, South Bend, Ind., The Serum Phosphatase in the Differential Diagnosis of Obstructive Jaundice.
Dr. Benjamin S. Kline and Mrs. D. Lloyd, Cleveland, Rapid Preparation of Serum for the Slide Tests for Syphilis.
Dr. Thomas Addis and Eloise Jameson, Ph.D., San Francisco, The Significance of Albumin-Globulin Ratios.

Dr. William Dock, professor of pathology, Stanford University School of Medicine, San Francisco, will address the annual banquet Saturday evening on "Ebb and Flow of Theories

About Pernicious Anemia." Dr. Carl W. Maynard, Pueblo, will deliver the presidential address on "Clinical Pathology Today."

American Heart Association.—The fourteenth scientific sessions of the American Heart Association will be held at the Sir Francis Drake Hotel, San Francisco, June 10-11. Dr. William J. Kerr, San Francisco, will deliver the presidential address on "Relief of Pain in Angina Pectoris Through Improved Filling of the Heart." Dr. Carl J. Wiggers, Cleveland, will give the annual address on "The Dynamics of Hypertension" and Dr. Eliot R. Clark, Philadelphia, the George Brown Memorial Lecture on "Certain Aspects of the Behavior of Peripheral Blood Vessels as Observed Microscopically in the Living Mammal." Other speakers will include:

- Dr. Wilhelm Dressler, Vienna, Austria, Dehydration Through Glycosuria, Experiments with Phlorizin as a Diuretic.
- Dr. Eric Ogden and Nathan W. Shock, Ph.D., Berkeley, Studies on Blood Pressure.
- Dr. Irvine H. Page, Oscar M. Helmer, Ph.D., and Dr. Kenneth G. Kohlstaedt, Indianapolis, The Isolation of Nicotine from Human Urine.

Examination in Pediatrics.—The American Board of Pediatrics announces the following dates for future examinations: Detroit, October 26 (Wednesday), preceding the meeting of Region III of the American Academy of Pediatrics; Rochester, N. Y., November 13 (Sunday), following the meeting of Region I of the American academy; Oklahoma City, November 15 (Tuesday), preceding the joint meeting of Region II of the academy with the Southern Medical Association. The board announces that all applications must be in the office of the secretary, Dr. Charles A. Aldrich, Winnetka, Ill., at least four months before an examination can be given. In view of the fact that the vast majority of those taking a second examination fail, the board ruled at its annual meeting in New York that applicants who have failed at one examination must wait two years before coming before the board for reexamination and must show evidence of further study or training in pediatrics to justify reexamination.

American Gynecological Society.—The sixty-third annual meeting of the American Gynecological Society will be held at the Grove Park Inn, Asheville, N. C., May 30-June 1, under the presidency of Dr. Noble Sproat Heaney, Chicago. The speakers will include:

- Dr. Albert H. Aldridge, New York, End Results of Treatment of 388 Cases of Placenta Praevia at the Woman's Hospital and Sloane Hospital for Women.
- Dr. George Van S. Smith, Brookline, Mass., Observations Concerning the Metabolism of Estrogens in Women.
- Dr. Karl M. Wilson, Rochester, N. Y., Results of the Treatment of Gonorrhea in Women by Sulfanilamide.
- Dr. Thaddeus L. Montgomery, Philadelphia, Problems in the Etiology and Prevention of Stillbirth.
- Dr. Virgil S. Counsellor, Rochester, Minn., Endometriosis: A Clinical and Surgical Review.
- Dr. George L. Streeter, Baltimore, Advances in Our Knowledge of the Early Primate Embryo.
- Dr. John Rock, Boston, Human Ovulation Electric Potentials.
- Dr. Carl R. Wegner, St. Louis, Pernicious Vomiting of Pregnancy.
- Dr. William C. Danforth, Evanston, Ill., The Place of Vaginal Hysterectomy in Present Day Gynecology.

Tours to San Francisco's Treasure Island.—Construction work on the Golden Gate International Exposition, which will open next year, has already reached the stage where it offers great interest to the public and each succeeding week will open new places of interest. The public and especially persons attending the annual session of the American Medical Association are invited to visit "Treasure Island." They may do so by taking the special Treasure Island ferries, which leave the Ferry Building every two hours from 7:30 a. m. to 3:30 p. m. week days and on Sunday every hour from 10 a. m. to 3 p. m. The round trip fare is 25 cents; there is also a 25 cent admission charge to Treasure Island. The tour about the island takes a little more than an hour. There are facilities on the island at present for dinner from \$1 and up, and for luncheons from 45 cents up. Treasure Island, in San Francisco Bay, is about a mile square. It is said to be the largest man made island. The architecture of the exposition buildings combines the elements of oriental and occidental design. When the fair is completed, one million flowers will be woven into a magnificent "magic carpet" on the west end of the island. Thirty-five foreign nations and three fourths of the states in the United States are planning to participate in this world's fair. Information can be obtained by addressing the Golden Gate International Exposition, 585 Bush Street, San Francisco.

National Tuberculosis Meeting.—The thirty-fourth annual meeting of the National Tuberculosis Association will be held in Los Angeles June 20-23 at the Biltmore Hotel. The preliminary program announced a symposium on tuberculosis in

industry, in which the speakers will be Drs. Anthony J. Lanza, New York; William A. Sawyer, Rochester, N. Y.; Clarence D. Selby, Detroit, and Mr. Donald E. Cummings, Denver. Another symposium will be on "Chronic Nontuberculous Infections of the Lung," with the following speakers: Drs. Robert G. Bloch, Chicago; Benjamin S. Kline, Cleveland; Jacob J. Singer, Los Angeles; Harold Brunn, San Francisco; Paul C. Samson, Oakland, and Ernest C. Dickson, San Francisco. Other speakers will include:

- Dr. Carleton B. Peirce, Ann Arbor, Mich., Roentgenologic Anatomy of the Chest.
- Dr. Charles Weiss, San Francisco, Cellular Proteinases in Inflammatory and Experimental Tuberculosis.
- Dr. Sherwood Moore, St. Louis, Body Section Radiography.
- Dr. Henry Stuart K. Willis, Northville, Mich., Treatment of Tuberculosis by Tuberculin Desensitization.
- Dr. Howard W. Bosworth, Los Angeles, Follow-Up of Collapse Therapy Cases.

Other symposiums will be presented on rehabilitation of the tuberculous—a community problem; transience and tuberculosis; poverty and tuberculosis with particular reference to the economic and social significance of high death rates in certain groups, and tuberculosis in the general practice of medicine with particular emphasis on case finding. The American Sanatorium Association and the National Conference of Tuberculosis Secretaries will hold their meetings June 20.

Registration Under Harrison Narcotic Act and the Marihuana Tax Act.—On or before July 1, every physician registered under the Harrison Narcotic Act or under the Marihuana Tax Act or under both must reregister with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the annual tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding \$2,000, or to imprisonment for not exceeding five years, or to both. The Commissioner of Internal Revenue has been lenient in the past in enforcing the criminal penalties provided by the Harrison Narcotic Act for tardy registration but continued disregard on the part of some physicians of the requirement of that act with respect to reregistration, and failure to comply with the registration requirement of the recently enacted Marihuana Tax Act will inevitably lead to criminal prosecutions. In recent years the commissioner has given some negligent or recalcitrant physicians the choice between paying substantial sums by way of compromise in lieu of the penalties for their offenses or, as an alternative, accepting criminal prosecution with resultant publicity and liability to fines of indefinite amounts and possibly imprisonment. This was an act of grace on the part of the commissioner; he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter. If the course that the commissioner has adopted does not produce the desired promptness in registration, he will have no recourse other than criminal prosecution to attain that result.

Government Services

Vacancies for Senior Medical Interns

The U. S. Public Health Service announces a number of vacancies to occur about July 1 for second year medical interns. Any physician, not over 30 years of age, who has graduated from an accredited medical college and who has completed, or will shortly complete, one year's internship in an approved hospital is eligible to apply. No written examination is required. Only applicants who are interested in the service as a career should respond. Appointments are to be effective on or about July 1 to vacancies at marine hospitals and federal penal and correctional institutions. Candidates appointed for duty at marine hospitals will receive a gross pay of \$1,800 each a year, from which a deduction of \$690 annually will be made if quarters, subsistence and laundry are furnished. Candidates who are assigned to the federal penal and correctional institutions will receive \$1,620 a year, from which about \$240 annually will be deducted if similar accommodations are furnished. Quarters, subsistence and laundry will be furnished in kind in every instance in which such allowances are available. The quarters for an intern are designed for the use of the individual himself and cannot be shared by dependents. Additional information may be obtained by addressing the Surgeon General, U. S. Public Health Service, Washington, D. C.

The Control of Marriages

Some sensation has been caused by the forecast by Sir Farquhar Buzzard, regius professor of medicine in the University of Oxford, of state control of all marriages in the next twenty-five years as a necessary measure to preserve the quality of the race. He was speaking in a series of lectures organized by the British Medical Association as a contribution to the National Fitness Campaign. He said that the state interfered with the liberty of the criminal because he was harmful to the community. But the consequences of ill advised marriages were equally damaging and much further reaching. Under present conditions the subnormal had every encouragement to reproduce the subnormal, while the normal and the supernormal bore the burden and were tempted and even forced to limit reproduction. We were confronted not only with a declining birth rate but with a population in which the unfit would outnumber the fit.

He put forward four proposals to avert this danger: 1. An intensive study of human heredity in a limited area. 2. More general education of children in biology, with special reference to heredity. 3. Some form of statutory authority for marriage involving the investigation of the personal and family health of the parties. 4. Some form of economic encouragement toward raising a fit family.

The Causes of Exophthalmos

At the annual congress of the Ophthalmological Society a discussion on the differential diagnosis of the causes of exophthalmos was introduced by R. Foster Moore. He estimates proptosis by standing behind the patient and making him look a little upward and tilt the head backward until the summit of the cornea first appears in view in front of the eyebrow. Deep palpation of the orbital contents with the little finger enables the front edge of the orbital mass sometimes to be felt, revealing its consistency and position. Tenderness might suggest inflammatory origin. At times when the tumor could not be felt the orbital fat was pushed forward and could be made to slip between the skin and the orbital margin. On palpation proptosis might be found reducible if due, for instance, to cavernous nevus; or pulsation due to arteriovenous aneurysm might be detected. Limitation of movements is more likely to be general in inflammatory than in neoplastic conditions. The immobility in inflammation is probably due to a toxic effect on the muscles, but paralysis is sometimes due to involvement of a nerve, such as the sixth, in cavernous sinus thrombosis. The palsies in thyrotoxicosis seemed to be due to persistent changes in the muscles.

Inflammatory causes provided the largest group of cases in the absence of exophthalmic goiter. In this disease a retracted upper lid might give a false appearance of exophthalmos. Metastatic tumors in the orbit were rare but should be first excluded in all cases of unilateral proptosis in an adult. Hemorrhage into the orbital cavity was frequently due to trauma but might occur spontaneously in hemophilia and scurvy or from physical causes, as in whooping cough or during birth. Arteriovenous aneurysm was one of the rarer causes of proptosis.

Dr. W. Russell Brain discussed the neurologic and general medical causes. A general rise of intracranial pressure might cause slight exophthalmos, but a much greater degree was produced by the pressure of a tumor growing near the orbit. Meningioma and slowly growing extracerebral tumors were

the most important. In such cases ptosis due to involvement of the third nerve or of the ocular sympathetic was common and helped to distinguish the exophthalmos from that of endocrine origin, which usually produced lid retraction. Intracranial aneurysms which were not syphilitic but due to a congenital defect in the muscular coat of the vessel might cause exophthalmos. Impaired venous return from the head, due to aortic aneurysm, intrathoracic neoplasm and even severe chronic emphysema, may cause exophthalmos, which might be associated with cyanosis and tortuosity of retinal veins. The syndrome of exophthalmic ophthalmoplegia had thrown light on the exophthalmos associated with goiter. It affected middle aged persons and males much more than did exophthalmic goiter. Progressive exophthalmos of one or both eyes was associated with external ophthalmoplegia, unilateral or bilateral. There was much edema of the lids and conjunctivae, which might protrude beyond the anterior border of the cornea. Hyperthyroidism was rarely severe and the condition might be progressive in patients with a subnormal basal metabolic rate after thyroidectomy. Recent experimental work on the thyrotropic hormone of the pituitary suggested that the exophthalmos might be due to overproduction of that hormone.

Bill to Regulate the Sale of Contraceptives

In the House of Commons leave was granted to introduce a bill to regulate the public display in shops of contraceptives and descriptive matter and to prohibit street trading in such articles. The member who introduced the bill referred to the widespread sale of contraceptives, particularly in populous areas. An inquiry showed that of 280 pharmacists only seven did not stock them. In addition a large number of shops were devoted to their sale, so as to become an offense to many who passed by. The bill dealt with the undue display of contraceptives and descriptive matter and sought to impose an age limit on persons to whom they might be sent.

The Presidency of the Royal College of Physicians

The office of president of the Royal College of Physicians has been held by Lord Dawson for the unusually long period of seven years, during which time he directed the activities of what was formerly considered simply an academic body into such practical directions as the promotion of research and postgraduate education. He has been succeeded by Dr. Robert Hutchison, consulting physician to the London Hospital and the Hospital for Sick Children, who is a well known clinical teacher and an authority on dietetics and pediatrics. His successful textbooks include the "Index of Treatment" (of which he is editor), "Clinical Methods," "Food and Dietetics" (which has reached an eighth edition), "Lectures on Diseases of Children" (which has reached a seventh edition), and "Elements of Medical Treatment" (third edition). In an age of faddists, in which the craze for novelty leads to the acceptance of much which is unsound, the new president is distinguished for his sturdy common sense. He is a Scot from the University of Edinburgh.

The International Congress of Psychotherapy

The tenth International Congress of Psychotherapy will be held at Oxford July 29-August 2 under the presidency of Prof. C. C. Jung. The International Medical Society of Psychotherapy, under whose auspices the congress is being held, has been in existence for fifteen years. Previous to 1937, when the congress was held at Copenhagen, the meetings took place in various German towns. This is the first meeting in an English-speaking country. The main subjects to be discussed are the psychology of the phases of life, psychotherapy and psychosomatic problems. The long contributions (forty-five minutes) will be in the form of read papers, but it is hoped that the shorter ones will be in the form of lectures based on notes. There will be ample time for discussion. Synopses of

the papers will be provided in the three languages of the congress, English, French and German. A small exhibition is being arranged to cover those sides of psychotherapeutic work which can be more conveniently demonstrated in graphic form. Physicians who have material which they think will be of special interest should communicate with the honorary secretary, Dr. E. B. Strauss, 81 Harley Street, London, W. 1. The registration fee is 17 shillings (\$3.50), which should be sent to the business secretary, Mr. H. Gibbs-Smith, 106 Brompton Road, London, S.W. 3, preferably by May 15. Members, both men and women, will be accommodated in Balliol and Somerville colleges at a cost of \$15, including all meals.

A Fatal Mistake

A mistake which resulted in the death of a peeress, aged 65, Lady Rankeillour, should be a warning to physicians never to order a powerful drug over the telephone. Her nurse rang up her physician, saying she had given her extra sleeping tablets and that she did not seem able to sleep. The nurse mentioned paraldehyde. She had not given it to a patient for sixteen years and did not know the dose. At the inquest she stated that she asked how she should give it and the physician telephoned to give a rectal injection of 6 ounces of paraldehyde in 8 ounces of paraffin. She wrote the message on the telephone block. When she told the pharmacist that she had to give 6 ounces as an injection he thought it was rather a large dose and that the maximum dose was 2 ounces. The injection was given and when the nurse found next morning that she could not rouse the patient she sent for the physician. In his evidence he stated that the dose of paraldehyde was determined by the weight of the patient—a drachm to the stone. In this case the patient weighed 10 stones (63.5 Kg.) and he ordered the nurse to give 6 drachms (22.5 cc.). It was a perfectly proper drug for a nurse to administer and he had not met one who did not know about it. A pathologist gave evidence that death was due to respiratory failure and was consistent with paraldehyde poisoning. The coroner recorded a verdict of "death by misadventure."

Attempt to Limit Prescription of Pharmaceutical Specialties

To check the indiscriminate prescription of so-termed pharmaceutical specialties for those covered by the social insurance law, the minister of labor has been obliged to limit the sums to be reimbursed to the insured when such "specialties" are prescribed for them. There are more than 10,000 of these special preparations in France and the traditional art of prescription writing is almost a dead issue. It cannot be denied that it is far easier to prescribe one of these "specialties" than to write a prescription. The patient is obliged to pay about 20 per cent more for the majority of these special preparations than a druggist would ask for an ordinary prescription with the same ingredients. For other "specialties" the patient here must pay far more than for the same drugs in the form of a prescription. The social insurance patient in the future will be reimbursed to the extent of 40 per cent for about 3,500 of 6,000 "specialties" but only 10 per cent for the remainder. Many of the pharmaceutical houses advertise in nonmedical journals and sing the praises of their special preparation over the radio, so that the socially insured have formed the habit of asking the attending physician to prescribe these unethically advertised preparations.

The profession here is also having its attention directed to another unethical mode of advertising employed by certain "specialty" makers. Every candidate for the medical degree in France must submit a thesis based on laboratory or clinical

observations. The cost of printing the thesis is often quite a burden for impecunious students, so that it has become a habit for some "specialty" manufacturers to defray the cost of printing the thesis provided it is based on the use of their particular "specialty" and the records of its use made on the record sheets of well known clinics.

Proposal to Punish Fee Splitting and Advertising

A public hearing will take place shortly before one of the committees of the French senate on a bill introduced by a former minister of public health, Mr. Sellier. The object of the proposed law is to penalize not only physicians who divide the fees received from patients referred to them for an opinion or operation but to put a stop to rebates given by orthopedic apparatus makers and druggists to physicians who send their patients. The Federation of Medical Syndicates, which has more than 20,000 members and look after public relations for the entire medical profession here, passed resolutions in 1932 condemning fee splitting in any form. At the February 20 meeting of the federation, the statement was made that many physicians have refused to divide the fees received from patients with the practitioner who sent them but that the application of this principle was not as widespread as might be wished for.

Another objective of the proposed Sellier law is an attempt to prevent newspapers from accepting advertisements of treatments by quacks. The extent to which such claims by quacks of all description appear in journals here is beyond all imagination. The ethical standard of the lay press in this country, in this respect, is much below that of reputable newspapers in other countries. Advertising by quacks is such a lucrative source of income that the proposed Sellier law to penalize it will meet with a great deal of opposition.

The Hereditary Factor in Hypertension

At the April 12 meeting of the Académie de médecine of Paris a paper was read on "Recent Studies on the Relation of Heredity in Cases of Hypertension." The author was Dr. G. Richard, who practices at Royat, the French health resort which specializes in the treatment of cardiovascular disturbances. That heredity is an important factor in hypertension has been previously reported by Weitz, Barach, Janeway and others. In association with Etienne, Dr. Richard in 1930 cited their study of 1,150 cases of hypertension. In 637, or 55.4 per cent, the familial factor was the only one responsible for the condition. Even in two thirds, or 21.9 per cent, in whom chronic nephritis, the artificial menopause and syphilis stood out as etiologic factors, there was also a history indicating the influence of heredity. This makes a total of nearly 70 per cent in which the disease was a familial one. This relatively high incidence holds true for a total of 5,000 cases reported by various authors.

In the present paper Dr. Richard reports 1,746 additional cases of hypertension. In 153, or 8.7 per cent, there was an absence of such a condition on the paternal and maternal sides. In 937, or 53.6 per cent, however, either the father or the mother had hypertension. In twenty-six, or 1.5 per cent, the grandparents suffered from this condition. In 265, or 15.2 per cent, although it was impossible to find a distinct hereditary factor, hypertension existed either in the sisters or in the brothers of the patients in 247 cases. In 223, or 12.7 per cent, of these more recently observed 1,746 patients, other etiologic factors were found to exist.

There exists a striking similarity as regards the sequels of hypertension in different members of the same family. In the majority of cases, if the father or mother died as the result of a cerebral hemorrhage, this was the cause of death in the children. This observation held true for successive generations as well as for other sequels of hypertension, such as angina pectoris.

Hereditary Diseases of the Visual Apparatus

One effect of the German eugenic legislation has been to bring into prominence all problems of heredity. Great interest therefore attaches to a recent discussion by Professor Dr. Gas-teiger of Frankfurt on the Main of hereditary disorders of the visual apparatus, published in *Forschungen und Fortschritte*. From a scientific point of view an eye is considered blind if the light perception is completely extinguished. In practice, however, one must recognize other concepts of the term blindness and, as the provisions of social legislation indicate, the more literal definition has had to be modified. For example, a traumatic injury to the eyes is considered as having caused blindness if the visual acuity has become so impaired that the person is unable to pursue his occupation and becomes dependent on others. The ophthalmologist Professor Axenfeld has pronounced the dictum that "persons unable to earn their living because of defective vision are blind." According to medical experience, total disability is present if visual acuity has been reduced to around 1/25 normal and cannot be improved by glasses. This definition of blindness is recognized by the social insurance and by the courts which are called on to apply the laws for prevention of hereditarily defective progeny. Furthermore, in the evaluation of blindness not only the central vision but the state of the field of vision must be considered.

Bilateral congenital atrophy of the optic nerve may be adduced as an example of inherited visual defect; this disorder, according to Professor Leber, is transmitted as a recessive characteristic. Other types of congenital atrophy also are based on heredity. Since, however, in addition to the heritable forms there are a whole series of nonhereditary forms of optic atrophy, thorough investigation of the immediate family and the ascendancy is necessary in each case before a diagnosis of an inherited condition is established.

The most important two hereditary diseases of the retina are retinitis pigmentosa and the modifications in the macula lutea associated with amaurotic family idiocy. Gray cataract is the chief congenital disorder of the anterior portion of the eye; this disease assumes many forms, and a many-sided differential diagnosis is necessary before the ultimate decision is reached. Then too there are the heritable changes in the cornea, such as megalocornea, microcornea and the nodular and reticular types of corneal degeneration. Also congenital defects of the uvea are recognized; albinism, for example. The author also mentions congenital motor disturbance such as ptosis and congenital nystagmus and, finally, color blindness. Red-green blindness and the rarer blue-yellow blindness are transmissible as recessive traits. Total color blindness, however, is usually related to nystagmus and high grade visual disturbances. Hereditary factors may also influence the pathogenesis of other anomalies: errors of refraction, myopia, hyperopia, astigmatism; but unless these defects are exceedingly severe they can usually be corrected by the wearing of glasses.

Protection of the Pregnant Workwoman

The 4,000 occupational groups of the German Workers' Front voted to introduce new regulations to become immediately effective for the protection of the pregnant workwoman. Accordingly the pregnant woman in industry now enjoys immunity from notice of dismissal for from eight to twelve weeks following delivery. After certification by a physician, the gravida may now discontinue work six weeks prior to confinement. If she so requests, the woman may be assigned to lighter tasks for from three to four months preceding confinement, but her regular wage must not be reduced. After she ceases work she receives the allowance customarily granted lying-in women, and any difference between that allowance and her regular wage is made good.

The Prevalence of Silicosis

In a recent article in the *Deutsche Bergwerkszeitung* it is stated that the average mortality from silicosis among miners is greater than one death a day. According to statistics for the years 1929-1936, accidental fatalities in the mining industry were reduced by one half during this period, whereas the death rate from silicosis constantly increased. The number of fatalities from silicosis in 1936 was 37 per cent greater than in the year 1929. Silicosis, therefore, constitutes a greater menace to the mine worker of today than the industrial accident.

Transplantation of Parathyroids

Drs. Rojas and Manfredi reported to the Sociedad Argentina de Biología in November 1937 the results of experiments in which they transplanted parathyroids in dogs. The implantation of parathyroids prevented the development of parathyroid tetany and maintained calcium and the phosphates of the blood plasma within normal values. The graft takes well below the capsule of the kidney and also below the muscles. Ten hours after implantation, revascularization of the graft can be seen by microscopic study. The central zone of the graft undergoes degeneration but the peripheral portion does not. Regeneration of the graft begins within twenty days of the operation and it is complete in three or four months. After eight, thirteen and fifteen months the transplanted parathyroids were removed with consequent development, within a few days, of tetany and lowering of the calcium and phosphates of the plasma.

Secretion of Ischemic Kidney Causes Hypertension

Reference has been made to experiments by Houssay and Fasciolo on experimental arterial hypertension induced by compression of the renal artery according to the technic of Goldblatt. Implantation of the ischemic kidney of a hypertensive dog into the neck of a dog recently nephrectomized and treated with chloralose increases the arterial pressure of the receptive dog from 30 to 75 mm. of mercury within five to ten minutes. The blood pressure of receptive dogs does not increase if the transplanted kidney is normal, whether the structure was removed from a normal dog or from a dog in a state of hypertension.

Professors Houssay and Fasciolo recently reported to the Sociedad Argentina de Biología results of further work. Implantation of twenty ischemic kidneys of dogs in hypertension increased the arterial pressure of the receptive dogs in all cases but two. That of twenty-five normal kidneys induced hypertension in only two dogs.

Dr. Taquini verified the fact that ischemic kidneys in place secrete substances that cause permanent arterial hypertension. The constrictive action of the citrated plasma of the blood of the renal vein of hypertensive dogs is more intense than that of the blood plasma of the carotid artery or of the jugular, intestinal and splenic veins of the same dog. The experiments prove that the ischemic kidney secretes substances that cause vasoconstriction. Ultrafiltrates of plasma of the renal vein become inactive, either because the active substances cannot pass through the filter or because they are absorbed by the proteins. The hypertensive action of the ischemic kidney is independent of the action of the adrenals. Implantation of ischemic kidneys in dogs without adrenals causes hypertension. Normal kidneys have an action which is antagonistic to hypertension. Hypertension increases more rapidly and is more intense and persistent when the compression of the renal artery is done on dogs which have only one kidney than on those which have both kidneys. Implantation of ischemic kidneys of dogs

in hypertension in the neck of nephrectomized dogs induces hypertension which does not take place or is slight if the implantation is done in dogs which have both normal kidneys. The results of the experiments show that the ischemic kidney secretes a substance that causes hypertension. It secretes the substance without any intervention from the adrenals. The substance that causes hypertension is neutralized, destroyed or eliminated by normal kidneys.

Personals

Dr. Alejandro Ceballos has been appointed professor of clinical surgery at the Facultad de Medicina of Buenos Aires, to succeed the late Prof. Pedro Chutro.

Drs. Miguel Sussini and José Tobías have been appointed president of the national department of public health and director of public health and sanitation of Buenos Aires, respectively.

Drs. J. A. Taiana, A. Introzzi and Jose M. Fernández have been given scholarships. Dr. Taiana will study surgery at Brussels University. Dr. Introzzi will study at the Mayo Clinic, Rochester, Minn., under a scholarship from the Comisión Nacional de Cultura. Dr. Fernández will study the pathology of leprosy in Paris and São Paulo under a scholarship from the Asociación Argentina para el Progreso de las Ciencias.

Deaths

Dr. Luis Tamini, professor of orthopedic surgery of the Facultad de Medicina of Buenos Aires, died Jan. 17, aged 56.

Dr. Nicolás Lozano died March 3, aged 74. He was a member of the Academia Nacional de Medicina, president of the Comisión Nacional de Asilos y Hospitales regionales, former president of the Red Cross in Argentina and secretary of the National Department of Public Health.

ITALY

(From Our Regular Correspondent)

March 25, 1938.

The Shock Therapy of Schizophrenia

At the convention of Italian neuropsychiatrists at Milan, the discussion of shock therapy of schizophrenia was limited to the two methods based on the work of Meduna and of Sakel. The term "shock therapy" is applied to either. The Meduna method consists in the administration to schizophrenic patients of from 4 to 5 cc. of a 10 per cent solution of metrazol by intravenous injection; epileptoid convulsions can thus be induced. The Sakel method is based on the production of a series of hypoglycemic episodes by intramuscular injection of insulin in daily doses up to 200 international units. The topic was developed by Professors Corberi, Lugiato and Medea, all of Milan, Cerletti of Rome and Riquier of Pavia. Professor Corberi reviewed the favorable results achieved by means of insulin shock in about forty cases at the Milan psychiatric hospital. Corberi's associate, Professor Lugiato, elucidated the economic aspect of the question; he stated that although routine application of the Sakel method would require an augmented hospital personnel it would ultimately result in an annual saving to his institution of some 250,000 lire (\$13,150), since a large number of schizophrenic patients would be discharged as cured.

Professor Cerletti, director of the Clinica Neuropsichiatrica di Roma, reported the following data from his experience: Of about thirty schizophrenic cases, both recent and chronic, which were treated by insulin shock, complete remission of symptoms and clinical cure took place in 42 per cent; amelioration satisfactory enough to permit return home was effected in 37 per cent and slight amelioration in 6 per cent. Experimental research has demonstrated that after repeated and profound insulin comas the brains of dogs undergo grave alterations, in part reversible and irreversible changes of a toxic character, in part changes more directly referable to disturbances of the

circulation. The author emphasized the first group of alterations, which tend to be constant. He adduced evidence to show that insulin coma entails the destruction of a certain number of neurons. The more labile frontal neurons bear the brunt of the whatever injury occurs. These particular neurons represent the latest cerebral formation to develop. It has been noted that in the human brain new neurons may form till the fortieth year. Accordingly there is nothing incongruous in the assumption that a large part of the psychic manifestations in schizophrenia correspond to modifications of functional, associative complexes of relatively recent origin and that therefore the mechanism of shock therapy is a sudden destruction of such complexes.

Professor Donaggio of Bologna expressed the opinion, based on histologic data, that insulin therapy induces histochemical alterations of the myelin.

Professor Mueller, director of the Psychiatric Hospital, Berne, reported the effects of insulin shock treatment on 495 schizophrenic patients at twenty-two different psychiatric institutions. In nearly 60 per cent of the more recent cases complete remissions occurred; about 40 per cent of all cases were considered cured. The mortality was about 1 per cent; recidivation was reported in less than 6.5 per cent.

Metrazol therapy, according to Meduna's method, also came in for ample discussion. The majority had experimented with this technic and declared themselves favorable to its use.

Bertolani described his experiments with convulsions induced by injections of ammonium chloride, with which he has elicited some favorable therapeutic results.

Rizzatti presented two schizophrenic patients who had been cured by the Moniz surgical treatment.

Research on Conditions Due to Low Temperatures

A center for research on the pathology and therapy of conditions due to the low temperatures of mountain regions has been established at Genoa. The activities concern research on thermal adaptation of man and animals to low temperatures, the pathology and treatment of lesions due to cold, particularly the use of short wave therapy, and the prophylaxis of such lesions, especially as the latter occur in the army and in connection with winter sports. Professor Sabatini, director of the new center, has obtained the collaboration of the army sanitary corps. Besides assigning a major of the medical corps to participate, the general staff of the army sanitary corps has ordered that soldiers severely enough affected with lesions due to cold to require hospitalization should be sent to the Military Hospital at Genoa, where special accommodations will be reserved.

Marriages

JAMES MURRAY ELLZEY JR., Chestnut Hill, Pa., to Miss Florence E. Haines of Frankford, April 8.

JOSEPH EDWARD GLADSTONE, Exmore, Va., to Miss Doretta Anne Roberts of Cape Charles, April 9.

ALBERT S. J. CLARKE, Clarendon, Ark., to Miss Ruth Shaw Smith of Nashville, Tenn., April 10.

WILLIAM BERNARD CARPENTER, Lovettsville, Va., to Miss Eilene Ward of Richmond, April 6.

JAMES LLOYD MIMS, Chester, S. C., to Miss Virginia Maynor of Winston-Salem, N. C., April 9.

RICHARD CAMPBELL MANSON to Miss Mary Kathryn Taylor, both of Richmond, Va., April 23.

CLARENCE MCNAIR WALLACE to Miss Ruth Allene Good, both of Hummelstown, Pa., April 1.

SYDNEY L. HARRIS, New Rochelle, N. Y., to Miss Natalie Crandall of New York in May.

WALTER SCOTT to Miss Mary Elizabeth Van Dyke, both of Sioux City, Iowa, March 17.

Deaths

Willson Orton Bridges, Omaha; University of the City of New York Medical Department, 1879; past president of the Nebraska State Medical Association, of the Omaha-Douglas County Medical Society and the Missouri Valley Medical Association; professor emeritus of medicine at the University of Nebraska College of Medicine, in 1911 associate dean and dean from 1914 to 1920; was a delegate to international medical congresses at Madrid, Budapest and London; in 1928 received the honorary degree of doctor of laws from the University of Nebraska; aged 81; died, March 4, in the Methodist Hospital of cerebral arteriosclerosis.

Charles Peter White * Wilmington, Del.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; past president of the Medical Society of Delaware and past president and secretary of the Newcastle County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Delaware and Wilmington General hospitals; ophthalmologist to the Delaware State Hospital, Farnhurst; aged 67; died, April 13, of heart disease.

Eustace Lincoln Fiske * Glendale, Calif.; Harvard University Medical School, Boston, 1886; member of the Massachusetts Medical Society; member, 1897-1899, and president in 1899 of the city council of Fitchburg, Mass., and for twelve years chairman of the board of health; visiting physician to the Burbank Hospital, Fitchburg, 1900-1922, and chairman of the board, 1910-1922; aged 77; died, March 20, in the Physicians and Surgeons Hospital of pneumonia.

Donald Stansbury Adams * Worcester, Mass.; University of Virginia Department of Medicine, Charlottesville, 1917; member of the New England Surgical Society; fellow of the American College of Surgeons; served during the World War; on the staffs of the Memorial Hospital, Worcester, Masonic Hospital, Shrewsbury, Webster District Hospital, Webster, and Harrington Memorial Hospital, Southbridge; aged 45; died, March 13, of a self-inflicted bullet wound.

William H. Kennedy, Indianapolis; Medical College of Indiana, Indianapolis, 1903; member of the House of Delegates of the American Medical Association in 1926; assistant professor of radiology at the Indiana University School of Medicine; member of the Indiana State Medical Association and the American Radium Society; aged 61; died, April 21, in the Robert W. Long Hospital of myeloid leukemia.

Thomas Marcus Bull * Naugatuck, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; past president of the New Haven County Medical Society; member and for many years president of the board of education of Naugatuck; on the staff of the Waterbury Hospital; aged 74; died, March 28, at his winter home in Winter Park, Fla., of pneumonia.

Logan Elmore Farthing * Wilmington, N. C.; University of North Carolina School of Medicine, Chapel Hill, 1906; past president and secretary of the New Hanover County Medical Society; past president and secretary of the staff of the James Walker Memorial Hospital; on the staff of the Bulluck Hospital; aged 58; died, March 31, of amebic colitis and perforation of the sigmoid with abscess.

Tolbert Barton Hinson * Enid, Okla.; Hospital College of Medicine, Louisville, 1905; past president of the Oklahoma State Hospital Association; fellow of the American College of Surgeons; on the staff of the Enid Springs Sanitarium and Hospital; served during the World War; aged 56; died, March 21, of pulmonary embolus following fracture of the hip.

William Carl Haupt, Brooklyn; University and Bellevue Hospital Medical College, New York, 1907; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; on the staff of the Brooklyn Eye and Ear Hospital and Norwegian Lutheran Deaconesses' Home and Hospital; aged 55; died, March 23.

Frank P. Patterson, Vancouver, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1898; member of the North Pacific Surgical Association and the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; aged 62; died, February 3.

Earl Aden Hogan, New Orleans; Northwestern University Medical School, Chicago, 1901; formerly assistant professor of medical aspects of life insurance, Tulane University Graduate School of Medicine; veteran of the Spanish-American and World wars; aged 63; died, March 16.

James Jackson Minot * Boston; Harvard University Medical School, Boston, 1878; honorary president and for many years vice president of the Boston Tuberculosis Association; consulting physician to the Massachusetts General Hospital; aged 85; died, April 30, of arteriosclerosis.

Samuel William Evans, Cleveland; Western Reserve University Medical Department, Cleveland, 1895; member of the Ohio State Medical Association; served during the World War; aged 63; died, March 14, in St. Alexis Hospital of coronary sclerosis and bronchopneumonia.

William Burnett, Montreal, Que., Canada; University of Bishop College Faculty of Medicine, Montreal, 1892; served with the Canadian Army during the World War; for many years on the staff of the Woman's General Hospital, Westmount; aged 67; died, March 8.

James Lindsay France * Wilmington, Del.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892; veteran of the Spanish-American War; on the staff of the Delaware Hospital; aged 67; died, March 14, of pneumonia.

Robert Henry Snowden * Medical Inspector, Commander, U. S. Navy, Bremerton, Wash.; University of Tennessee College of Medicine, Memphis, Tenn., 1915; entered the navy in 1917; aged 47; died, February 4, on board the U. S. S. *Mississippi* of thrombosis.

Frederick William Heysett * Ludington, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; past president of the Mason County Medical Society; on the staff of the Paulina Stearns Hospital; aged 68; died, March 12.

John Andrew Brewin, Everett, Mass.; North Carolina Medical College, Davidson, 1904; member of the Massachusetts Medical Society; formerly chairman of the board of health; aged 61; died, March 7, at the Baker Memorial Hospital, Boston, of pneumonia.

Arthur Richmond Crandell * Taunton, Mass.; Harvard University Medical School, Boston, 1896; member of the New England Pediatric Society; for many years member of the school board; on the staff of the Morton Hospital; aged 67; died, March 18.

Calvin Daniel Christ * Orlando, Fla.; College of Physicians and Surgeons, Baltimore, 1905; past president of the Orange County Medical Society; on the staff of the Orange General Hospital; at one time county physician; aged 59; died, March 19.

Edgar Vernon Henry * Beaumont, Texas; Chicago College of Medicine and Surgery, 1915; served during the World War; on the staffs of the Hotel Dieu Hospital and St. Therese Hospital; aged 46; died, March 19, in the John Sealy Hospital, Galveston.

Frederick Ernst Buchen, Darby, Mont.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; formerly vice president of the Medical Association of Montana; aged 72; died, March 1, at Hamilton of cirrhosis of the liver and nephritis.

Pearl S. Windham * Saginaw, Mich.; Detroit College of Medicine, 1902; past president of the Saginaw County Medical Society; fellow of the American College of Surgeons; on the staff of the Saginaw General Hospital; aged 62; died, February 23.

Harry William Dickerson, San Diego, Calif.; Washington University School of Medicine, St. Louis, 1904; member of the California Medical Association; aged 63; died, March 24, in the Mercy Hospital of Hodgkin's disease and secondary anemia.

John Andrew Heinlein, Bridgeport, Ohio; Jefferson Medical College of Philadelphia, 1886; formerly health officer, postmaster, and member of the school board; aged 76; died, March 3, of bronchopneumonia, acute bronchitis and arteriosclerosis.

Victor Biart * Captain, U. S. Army, retired, Norwalk, Conn.; Missouri Medical College, St. Louis, 1876; entered the army as an assistant surgeon in 1878 and retired as captain in 1891 for disability in line of duty; aged 90; died, March 26.

George A. Brown, Banner Elk, N. C.; University College of Medicine, Richmond, 1897; member of the Medical Society of the State of North Carolina; aged 68; died, March 28, of acute dilatation of the heart, hypertension and nephritis.

Robert Oliver Baldwin, Oakland, Calif.; University of California Medical Department, San Francisco, 1895; formerly county coroner; aged 72; died, March 28, in the Peralta Hospital of coronary thrombosis and secondary anemia.

J. Davis Forster, New Smyrna, Fla.; Barnes Medical College, St. Louis, 1896; member of the Florida Medical Association; served during the World War; aged 67; died, March 22, in the Veterans Administration Facility, Bay Pine.

Wilson Luther Gleason, Fairview, Okla.; Drake University College of Medicine, Des Moines, Iowa, 1884; Bennett College of Eclectic Medicine and Surgery, Chicago, 1888; aged 79; died, March 28, of cerebral hemorrhage.

Ben Neal Ard, Dallas, Texas; Baylor University College of Medicine, Dallas, 1915; member of the State Medical Association of Texas; served during the World War; aged 53; died, March 29, of carcinoma of the esophagus.

John Otto Ficke, Salem, Mo.; Beaumont Hospital Medical College, St. Louis, 1900; member of the Missouri State Medical Association; county coroner; aged 66; died suddenly, March 23, of cerebral hemorrhage.

Thomas Emmett Farrell, Seneca, Wis.; Milwaukee Medical College, 1901; member of the State Medical Society of Wisconsin; served during the World War; aged 61; died, February 2, of coronary thrombosis.

Charles Frederick Colfax Hancock Ⓢ Jeffersonville, Ind.; Medical College of Ohio, Cincinnati, 1887; formerly member of the state legislature; aged 71; died, March 27, of cerebral hemorrhage and arteriosclerosis.

Cecil Denham, Buckhannon, W. Va.; College of Physicians and Surgeons, Baltimore, 1901; served during the World War; formerly superintendent of the Weston (W. Va.) State Hospital; aged 64; died, March 4.

Sylvan M. Pearman, Pasadena, Calif.; Homeopathic Medical College of Missouri, St. Louis, 1886; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 79; died in March of diabetes mellitus.

J. P. Heath, Fishers, Ind.; College of Physicians and Surgeons of Indiana, Indianapolis, 1877; Medical College of Indiana, Indianapolis, 1879; aged 85; died, March 2, in the Methodist Hospital, Indianapolis.

Henry Herman Claus Heuck, Orange, Calif.; Chicago College of Medicine and Surgery, 1912; formerly associated with the U. S. Public Health Service; aged 54; died, March 30, of cerebral hemorrhage.

Theodule Bruneau, Montreal, Que., Canada; Laval University Medical Faculty, Montreal, 1896; professor of clinical medicine at the University of Montreal Faculty of Medicine; aged 64; died, February 9.

Clarence Edward Persons, Marshall, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877; member of the Minnesota State Medical Association; aged 90; died, January 4.

Robert Park Adams, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1904; member of the Medical Association of Georgia; aged 60; died, March 14, of chronic nephritis and arthritis.

Joseph Churchill Patton, Toronto, Ont., Canada; M.B. University of Toronto Faculty of Medicine in 1888 and M.D. Victoria University Medical Department, Coburg, 1888; aged 87; died, February 7.

Andrew Y. Hatchett, Bloomfield, Ky.; Kentucky School of Medicine, Louisville, 1891; aged 72; died, March 23, in the Kentucky Baptist Hospital, Louisville, of pulmonary embolism and diabetes mellitus.

Victor Eugene Putnam, San Francisco; University of California Medical Department, San Francisco, 1896; member of the California Medical Association; aged 66; died, March 11, of cerebral hemorrhage.

Joseph Georges Albert Bouvier, St. Albert, Ont., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1908; aged 56; died, February 12.

Joseph C. R. Doggett Ⓢ Crane, Mo.; Barnes Medical College, St. Louis, 1905; also a druggist; aged 56; died, March 29, in St. John's Hospital, Springfield, of nephritis, arteriosclerosis and hypertension.

Granville Howard Twining Ⓢ Mobridge, S. D.; Rush Medical College, Chicago, 1910; fellow of the American College of Surgeons; surgeon to the Mobridge Hospital; aged 61; died, February 4.

John Sidney Branch, Lettsworth, La.; University of Louisville (Ky.) Medical Department, 1881; member of the Louisiana State Medical Society; aged 78; died, March 8, of coronary thrombosis.

James Robert Floyd, Fort Worth, Texas; Memphis (Tenn.) Hospital Medical College, 1887; member of the State Medical Association of Texas; aged 77; died, March 31, of pneumonia.

Herbert Charles Stanton, Clifton Heights, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; medical director of the Burn Brae Hospital; aged 63; died, February 8.

Louis C. Mullikin, Los Angeles; Jefferson Medical College of Philadelphia, 1892; aged 77; died, March 6, in the Los Angeles County General Hospital of hypertensive heart disease.

M. G. Herrell, Powell Station, Tenn.; Tennessee Medical College, Knoxville, 1906; member of the Tennessee State Medical Association; county physician; aged 58; died, February 4.

Edward Hayden Ⓢ Cashmere, Wash.; National Medical University, Chicago, 1907; Chicago College of Medicine and Surgery, 1908; aged 66; died, March 9, of coronary disease.

Elmer Ellsworth Hendershot, Tecumseh, Mich.; University of Michigan Department of Medicine and Surgery, 1886; bank president; aged 76; died, March 8, of coronary thrombosis.

Howard E. Ezell, Oliver, Ga.; Atlanta College of Physicians and Surgeons, 1902; formerly mayor; aged 59; died, March 15, of essential hypertension and cerebral hemorrhage.

George Albert Slocumb, Cohasset, Mass.; Boston University School of Medicine, 1880; served the Hahnemann Hospital, Worcester, in various capacities; aged 80; died, January 31.

Robert Lawson Hope, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1881; past president of the county board of education; aged 78; died, February 25.

Deddo H. W. Borgman, Louisville, Ky.; University of Louisville Medical Department, 1894; member of the Kentucky State Medical Association; aged 65; died, January 23.

William E. Wells, Lakewood, Ohio; Homeopathic Hospital College, Cleveland, 1885; formerly on the staff of the Huron Road Hospital, Cleveland; aged 76; died, February 6.

John William Folk, Newberry, S. C.; Medical College of the State of South Carolina, Charleston, 1874; formerly member of the state legislature; aged 86; died, February 3.

Frederick Burr Dezell Ⓢ Lynn, Mass.; Albany (N. Y.) Medical College, 1896; on the courtesy staff of the Lynn Hospital; aged 70; died, February 2, of aortic stenosis.

Melville G. Evans, Portland, Ore.; St. Louis College of Physicians and Surgeons, 1904; aged 65; was found dead in his garage, March 29, of carbon monoxide poisoning.

Herbert Henderson Sinclair, Walkerton, Ont., Canada; University of Toronto Faculty of Medicine, 1894; Trinity Medical College, Toronto, 1894; aged 67; died, February 1.

John H. Riera, Fontainebleau, France; University of Pennsylvania Department of Medicine, Philadelphia, 1885; formerly a resident of Philadelphia; aged 78; died, March 5.

Leverette H. Crapp, St. Louis; St. Louis College of Physicians and Surgeons, 1900; aged 64; died, March 23, of hemiplegia, arteriosclerosis and cerebral hemorrhage.

William Francis Holmes, Florence, S. C.; Howard University College of Medicine, Washington, D. C., 1910; aged 69; died, March 9, of influenza and pneumonia.

Joseph P. Hennerich, St. Louis; St. Louis Medical College, 1887; member of the Missouri State Medical Association; aged 78; died, March 30, of coronary occlusion.

John Franklin Anderson, Chicago; Northwestern University Medical School, Chicago, 1930; member of the Illinois State Medical Society; aged 45; died, March 19.

Emery Milton Goodwin, East Cleveland, Ohio; Western Reserve University Medical Department, Cleveland, 1895; aged 69; died, March 23, of carcinoma of the hand.

Walter Bozeman Moore, Repton, Ala.; Birmingham Medical College, 1903; member of the Medical Association of the State of Alabama; aged 63; died, January 16.

Leidy L. Cope, Hatfield, Pa.; Jefferson Medical College of Philadelphia, 1883; formerly member of the board of health and school board; aged 78; died, February 8.

Francis O. Ritter, Allentown, Pa.; University of Maryland School of Medicine, Baltimore, 1881; formerly bank president; aged 79; died, February 11, of cholecystitis.

Evan Ardiel, Washtucna, Wash.; Western University Faculty of Medicine, London, Ont., Canada, 1906; aged 57; died, March 21, in Portland, Ore., of thrombosis.

John Henry Chapman, Tanner, W. Va.; University of Louisville (Ky.) Medical Department, 1895; served during the World War; aged 71; died, February 20.

Ezra McKnight Davis, Mayesville, S. C.; George Washington University School of Medicine, Washington, D. C., 1908; aged 54; was shot and killed, March 11.

Edwin Garfield Festerling Ⓜ Milwaukee; University of Pennsylvania School of Medicine, Philadelphia, 1911; aged 57; died, March 25, of coronary thrombosis.

Samuel Q. Bass, Cincinnati; Pulte Medical College, Cincinnati, 1896; served during the World War; aged 65; died, March 3, of hypertensive heart disease.

Theodore F. H. Spreng, Los Angeles; Hahnemann Medical College and Hospital, Chicago, 1879; aged 85; died, March 27, of arteriosclerosis and hypertension.

Charles Theodore Cutting, Los Angeles; Hahnemann Medical College and Hospital of Philadelphia, 1898; aged 61; died, March 7, of rupture of the heart.

C. F. Guthrie, Alfred, Ohio; College of Medicine and Surgery, Chicago, 1895; aged 78; died, March 3, of mitral regurgitation and parkinsonian disease.

John James Bourn, Palo Alto, Calif.; Rush Medical College, Chicago, 1896; aged 67; died, March 13, in the Palo Alto Hospital, of disease of the adrenals.

William Lee Calvert, Louisville, Ky.; Louisville Medical College, 1906; served during the World War; aged 53; died, March 21, of cerebral hemorrhage.

George P. Sanders, Stephens, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; member of the Arkansas Medical Society; aged 64; died, January 15.

Frances Harriet Drew, Quincy, Mass. (licensed in Massachusetts under the Act of 1907); aged 85; died, March 12, of myocarditis and bronchopneumonia.

John Azerre Flowers, St. Louis; Chicago Medical School, 1918; Meharry Medical College, Nashville, Tenn., 1920; aged 54; died, March 25, of peritonitis.

Thomas L. Hood, West Monroe, La.; Louisville (Ky.) Medical College, 1887; formerly mayor and member of the state senate; aged 75; died, January 9.

Jacob Wade Paul Goudy, Bristol, Maine; University of Vermont College of Medicine, Burlington, 1896; aged 72; died, March 2, of coronary thrombosis.

William Thomas Little Ⓜ Paducah, Ky.; University of Louisville School of Medicine, 1907; served during the World War; aged 53; died, February 2.

Jesse Vincent Gilbert, Maricopa, Calif.; College of Physicians and Surgeons, Baltimore, 1896; aged 74; died, March 6, of carcinoma of the stomach.

Clifford E. Flaningam, Las Cruces, N. M.; University of Louisville (Ky.) Medical Department, 1915; aged 48; died, March 17, of heart disease.

William D. Corse, Baltimore; University of Maryland School of Medicine, Baltimore, 1887; aged 71; died, March 13, of carcinoma of the tongue.

Nathaniel Ellis Oliver, Costa Mesa, Calif.; Chicago Medical College, 1880; aged 81; died, February 27, of chronic myocarditis and arteriosclerosis.

Harlan L. Byington, Risingsun, Ohio; Physio-Medical Institute, Cincinnati, 1876; aged 86; died, March 29, of myocarditis and mitral regurgitation.

John T. Gill, Echo, Minn.; New York Homeopathic Medical College, New York, 1886; aged 79; died, February 21, of acute cardiac dilatation.

Carl Peter Fallen, Norfolk, Conn.; Dartmouth Medical School, Hanover, N. H., 1893; aged 75; died, March 30, of cerebral arteriosclerosis.

Isaac Cecil Walker Ⓜ Marion, Ill.; St. Louis College of Physicians and Surgeons, 1897; aged 67; died, February 26, of pulmonary tuberculosis.

Izatus L. Smith, Syracuse, Neb.; Kentucky School of Medicine, Louisville, 1890; aged 83; died, February 10, of cholangitis and cholelithiasis.

Peter Leroy Hartman, Colon, Mich.; Jefferson Medical College of Philadelphia, 1890; aged 71; died, March 30, of cerebral hemorrhage.

Claude George Burgess Ⓜ Detroit; Detroit College of Medicine, 1903; aged 60; died, March 14, in the Harper Hospital of pneumonia.

Lynn Moore Barnes, Decatur, Ill.; Harvard University Medical School, Boston, 1900; aged 64; died, March 13, of chronic nephritis.

Oliver Fernald Cushing, Thomaston, Maine; Medical School of Maine, Portland, 1883; aged 76; died, March 17, of angina pectoris.

Edward R. Flinchbaugh, Cincinnati; Cincinnati College of Medicine and Surgery, 1895; aged 69; died, March 7, of arteriosclerosis.

Lawrence A. Wagner, Youngstown, Ohio; Marion-Sims College of Medicine, St. Louis, 1899; aged 73; died, March 21, of pneumonia.

William D. Hutto, Greenwood, S. C.; Medical College of the State of South Carolina, Charleston, 1882; aged 79; died, February 25.

Aslan Nacciarone, New York; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1898; aged 66; died in February.

Harlin Clyde Henderson, Carpinteria, Calif.; Rush Medical College, Chicago, 1896; aged 63; died, March 6, of cerebral hemorrhage.

Joshua Newton Mack, Halifax, N. S., Canada; Bellevue Hospital Medical College, New York, 1875; aged 93; died, February 7.

Edward Sims Hawkins, Cedar Hill, Tenn.; University of Louisville (Ky.) Medical Department, 1880; aged 88; died, January 15.

Isaac Newell Eastman, Groton, Vt.; Kentucky School of Medicine, Louisville, 1893; aged 71; died, March 16, of chronic nephritis.

Robert W. Chalfant, Bellefontaine, Ohio; Eclectic Medical Institute, Cincinnati, 1882; aged 85; died, March 1, of diabetes mellitus.

John Becker, Milwaukee; Fort Wayne (Ind.) College of Medicine, 1890; aged 84; died, March 11, of cerebral hemorrhage.

Charles T. Shinn, Stonehurst, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 86; died, February 7.

John Pinkham Rice, San Antonio, Texas; American Medical College, St. Louis, 1877; aged 84; died, February 23, of senility.

Warren T. Binion, Cumby, Texas (licensed in Texas, under the Act of 1907); aged 82; died, March 21, of carcinoma of the larynx.

Humberto Cuen, Claremore, Okla.; St. Louis University School of Medicine, 1934; aged 28; died, March 28, of heart disease.

Ira Wickliff Bouldin, Santa Ana, Calif.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 80; died, March 30.

Robert French Ferguson, Clarksville, Tenn.; University of Nashville Medical Department, 1876; aged 82; died, January 21.

D. Iris Cochran, Hamilton, Ohio; Cleveland Homeopathic Medical College, 1903; aged 60; died, March 20, of carcinoma.

Walter Lewis Hallet, Brockton, Mass.; Harvard University Medical School, Boston, 1886; aged 78; died, March 9.

Henry Franklin Zink, Tulsa, Okla.; Eclectic Medical University, Kansas City, Mo., 1906; aged 70; died, February 21.

John Franklin Clark, Rayville, Mo.; Northwestern Medical College, St. Joseph, 1893; aged 82; died, March 23.

Henry D. Rinehart, Pasadena, Calif.; Long Island College Hospital, Brooklyn, 1886; aged 74; died in February.

Charles De Witt Hibbetts, Naples, Texas; Barnes Medical College, St. Louis, 1904; aged 58; died, March 1.

Samuel Lerner, Quincy, Mass.; St. Louis College of Physicians and Surgeons, 1921; aged 42; died, January 1.

George M. Bradford, Mount Morris, Pa.; Pulte Medical College, Cincinnati, 1889; aged 74; died, February 18.

Eugene Maurice Griffin, Crider, Ky.; Hospital College of Medicine, Louisville, 1897; aged 68; died, March 10.

Eugene Coffeen, Redondo Beach, Calif.; Hering Medical College, Chicago, 1900; aged 84; died, March 23.

John Angus Garrard, Roberta, Ga.; Birmingham (Ala.) Medical College, 1913; aged 58; died, March 15.

J. F. Evans, Stephens, Ark. (licensed in Arkansas in 1903); aged 68; died, March 14, of acute myocarditis.

L. A. Hill, Hot Springs National Park, Ark. (licensed in Arkansas in 1903); aged 65; died, March 21.

W. P. Wilson, Ocala, Fla.; Meharry Medical College, Nashville, Tenn., 1897; aged 68; died, February 25.

Bureau of Investigation

THE TRENCH EPILEPSY CURE FRAUD

A Bromide Mixture Sold from Toronto and Dublin is
Denied the U. S. Mails

Trench's Remedies, Ltd., at Dublin, Ireland, and Toronto, Canada, was declared by the Postoffice Department to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses and was excluded from the United States mails on March 30, 1938.

More than a quarter of a century ago THE JOURNAL published an article in this department on "Trench's Remedy" and gave the essential facts regarding it, together with the results of analyses made by the British Medical Association. It was

TRENCH'S REMEDY

FOR

Epilepsy and Fits

WITH DIRECTIONS FOR TREATMENT

AND

Testimonials, Certificates, Etc.

TRENCH'S REMEDY

TRADE

MARK

TRENCH'S REMEDIES, Limited, 33 South Frederick Street,
DUBLIN, IRELAND.

AND

107 St. James' Chambers, Corner of Church and Adelaide Streets,
TORONTO, CANADA

shown then that the stuff came in two forms: a liquid as sold in the British Isles and a powder as sold in the United States, as well as in Canada and in other parts of the British empire.

The liquid contained 70 grains of potassium bromide and 10 grains of ammonium bromide to the fluidounce, with sugar to sweeten and fuchsin to color it. The powder was a mixture of 61 parts of potassium bromide and 39 parts of brown sugar.

The memorandum of the Solicitor of the Postoffice Department, recently sent to the Postmaster General recommending the issuance of a fraud order, states that Trench's Preparation has been advertised "in various publications throughout the United States." The address given in such advertisements is usually that of the Toronto branch of this mail-order quackery. Those who answer the advertisement receive a form letter from Trench's Remedies, Ltd., in which the prospective victim is told, in effect, that the use of the Trench product will cure epilepsy.

Part of the advertising ballyhoo is a "Certificate of Analysis" said to have been given by "Granville H. Sharpe, F.C.S., Analytical and Consulting Chemist," London, England. The "analysis" gives no information regarding the composition of the "patent medicine" but does describe it as a "skillfully and judiciously compounded preparation." As THE JOURNAL pointed out twenty-six years ago, Granville H. Sharpe was a faker who

for years made a business of furnishing—at a price—"certificates" that could be used as advertising assets.

The government chemists found the Trench preparation to be essentially what the British Medical Association had reported in 1912. Because a mixture of bromides and brown sugar will not cure epilepsy or restore epileptics to normal health, as claimed, the Trench business was declared a fraud.

THE LYTHEROL FRAUD

George P. Seiler's Lyteric Products Company
Debarred from the U. S. Mails

"Lytherol" was sold through the mails as a cure for hay fever, head colds, sinusitis and passive congestion of the nasal canal. It was put on the market by one George P. Seiler, a real estate salesman of New Orleans. Government chemists reported that Lytherol consisted of "fatty oil, small amounts of oleic acid and traces of oil of lavender." It was to be dropped into the nostrils and "snuffed up" as far back as possible.

Seiler claimed to have learned of this wonder from a Greek whom he met in New York several years ago. The preparation was found to have neither germicidal nor even antiseptic action but was merely slightly emollient.

Seiler submitted no evidence for the claims made for his nostrum and made no appearance at the hearing. He contented himself with a mere denial of the charge of fraud. The charge, however, stood, and on March 12, 1938, a fraud order was issued against the Lyteric Products Company.

Correspondence

THERAPY OF JAUNDICE

To the Editor:—Regarding the article on the "Therapy of Icterus (Jaundice)" (THE JOURNAL, March 5, p. 732) I believe that section E, paragraph 3, of treatment, in which it is stated regarding the use of intravenous dextrose that it must be given intravenously as then the glycogen is deposited in the liver more liberally than when the sugar is taken by mouth, should be changed to:

In patients who cannot take oral dextrose because of vomiting or drowsiness it must be given intravenously, but in patients who can take and retain dextrose by mouth it should be given orally, since this method is simpler and more convenient. The glycogen deposit in the liver is practically the same in the two methods.

This suggestion is advanced on the basis of Althausen's paper on "Deposition of Glycogen in Normal and in Experimentally Damaged Livers After Oral and Intravenous Administration of Dextrose" in the *American Journal of Digestive Diseases*, January 1938, page 752, which seems to indicate the effectiveness of giving dextrose in either way when the liver is damaged.

FRANKLIN W. WHITE, M.D., Boston.

TREATMENT OF GIARDIASIS

To the Editor:—In THE JOURNAL of March 12, page 834, I read with interest your answer on the treatment for Giardia (Lamblia). There is a treatment against this parasite which has been successfully used in hundreds of cases. It was first suggested and tried by Galli-Valerio, professor of parasitology at the University of Lausanne (Galli-Valerio, Bruno: La lamblia et son traitement par l'atébriane, *Schweiz. med. Wchnschr.* 67:1121 [Dec. 11] 1937. Tecon, R. M.: La lamblia et son traitement, *J. belge gastro-entérol.* 5:315 [April] 1937; La lamblia et son traitement par l'atébriane, *Schweiz. med. Wchnschr.* 68:247 [March 12] 1938). The drug is a salt of amino acridine, which is used in the treatment of malaria and is known under the name of atabrine. The dose usually ordered is 0.1 Gm. three times a day for five days, but I showed recently that complete destruction of the parasites and cure of the patient could be obtained with 0.1 Gm. once a day for two or three days.

RENÉ MAURICE TECON, M.D., Lausanne, Switzerland.

NERVE INJURIES AND DEXTROSE

To the Editor:—In the article March 26 by Dr. George B. Hassin there are references, both in the heading of the article and in the text, to nerve injuries caused by intravenous injections of dextrose. After reading the article I am at a loss to understand why dextrose was included as part of the cause of these injuries, since the case records seem to indicate quite clearly that the injuries were incident to the injections and not to the substance injected.

HOMER K. NICOLL, M.D., Chicago.

NOTE.—The letter was referred to Dr. Hassin, who writes:

To the Editor:—It would be absurd to claim that dextrose injected intravenously caused the nerve injuries in the eight cases quoted in my article. Among the probable causes of the injuries—direct lesion to the nerves, edema, pressure or other factors—I did not mention dextrose. I included it in the caption because no other substance is used so extensively, in so large amounts and through so many hours as the solutions of dextrose. Any other substance injected intravenously under similar circumstances would give complications as described, which, of course, like the injections of dextrose, would be accidental and not caused by the injected substance itself.

GEORGE B. HASSIN, M.D., Chicago.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INTRADERMAL AND PRECIPITIN TESTS FOR TRICHINOSIS

To the Editor:—Please give me some information regarding the Bachman intradermal test for trichinosis, including the technic and information as to where I can obtain the material for making the test.

ALBERT A. SCHULTZ, M.D., Fort Dodge, Iowa.

ANSWER.—The antigen in the Bachman intradermal test for trichinosis consists of an extract of trichinella larvae in Coca's solution (sodium chloride 0.7 per cent, sodium bicarbonate 0.05 per cent and phenol [carbolic acid] 0.4 per cent in distilled water). The test is done as follows: 0.1 cc. of a 1:10,000 dilution in Coca's solution of the trichinella antigen is injected intradermally into the flexor surface of the forearm and the same amount of Coca's solution injected into the other arm as a control. A delayed or immediate type of reaction may develop, depending on the stage of the illness. During the first week of the disease there is usually a delayed type of reaction consisting of erythema, and edema at the site of the injection from twelve to twenty-four hours after injection. The immediate type of reaction usually is obtained during the second week of the injection. Within five minutes after the injection a blanched wheal appears, sometimes with pseudopodia running out from it. A pronounced area of erythema surrounds the wheal. The reaction reaches its maximum in one hour and then gradually subsides. This type of reaction may be elicited months and years after the acute illness has subsided. A more reliable test in the diagnosis of trichinosis, and utilizing the same antigen in a dilution of 1:100, is the precipitin test. This is done by overlaying 0.5 cc. of blood serum in a small tube with an equal amount of the 1:100 antigen. A control test is run in a second tube with the same amount of serum overlaid with Coca's solution. The tubes are placed in a water bath at 37.5 C. for one hour. A positive test shows a white ring at the junction of the antigen and serum. This test usually becomes positive during the third week of the illness. At present there is no available commercial preparation of the antigen. The method of preparing the antigen and results of its clinical application are discussed in the following:

Augustine, D. L., and Theiler, Hans: Precipitin and Skin Tests as Aids in Diagnosing Trichinosis, *Parasitology* 24: 60 (March) 1932.
Spink, W. W.: Trichinella Antigen: Further Observations on Its Use in the Diagnosis of Trichinosis, *New England J. Med.* 216: 5 (Jan. 7) 1937.

DESENSITIZATION IN ARRESTED PULMONARY TUBERCULOSIS

To the Editor:—A woman aged 21, a school teacher, has had symptoms of hay fever for the last ten years within two days of August 15, with the exception of 1937. Last summer they occurred July 15 and were especially severe, lacrimation being so profuse that she could not see. I advised a trip 150 miles north, where ragweed is scarce. I have no information regarding the presence of grasses in that locality, but in two days after arriving she was symptom free. Symptoms returned immediately on return six days later. About August 1 she again drove north for relief and remained two weeks symptom free, at which time she returned, only to suffer from hay fever until late in September. Her pollen scratch tests at present are as follows: elm, 1 plus; oak, trace; blue grass (June), 4 plus; timothy, 3 plus; red top, 4 plus; giant ragweed, 4 plus; short ragweed, 4 plus. Corn smut, yeast and alternaria are negative. The past history is negative with the exception that in 1935 she was bedridden with pleurisy. Although there are a few subcutaneous rales in the right apex, the x-ray report states "pulmonary tuberculosis apparently arrested." Is there any contraindication to desensitizing three years after active pulmonary tuberculosis has been arrested? Would a shotgun mixture of mixed grasses and short and tall ragweed defeat its own purpose? If not, what concentrations would you advise? Have you any other suggestions or comments regarding desensitization of this patient?

M.D., New York.

ANSWER.—Although the patient reacts to ragweed and grass pollens and is probably clinically sensitive to both of these types of pollens, the history would indicate that another type of sensitivity is present. Seasonal rhinitis from the middle of July to the middle of August in the territory under discussion would be difficult to explain on the basis of pollen allergy. The patient is probably sensitive to fungi in spite of the fact that tests to corn smut, yeast and alternaria were reported as negative. More thorough investigation for possible mold sensitization should be made. This should include scratch tests with a more inclusive list of fungi, such as alternaria, aspergillus, penicillium, hormodendrum, monilia, chaetomium, mucor, cephalosporium, fusarium and smut. If no reactions are obtained, intradermal tests with the same fungi should be tried.

There are no contraindications for desensitization in an arrested case of pulmonary tuberculosis. As a matter of fact many phthisiologists and allergists are of the conviction that active symptoms of hay fever and asthma may activate a tuberculosis and therefore anything that can be done to minimize these allergic symptoms may be of appreciable benefit to the patient.

It is not advisable to mix the grass pollens with the ragweed pollens, chiefly for the reason that the difference in the seasons will necessitate a differing progression of doses for the two types of pollen. It is best to have the grass pollens in one mixture and the ragweed pollens in another. The two injections may be given at the same visit, one in the right arm and the other in the left. The average patient may begin with 0.05 cc. of 1:10,000 of these pollen extracts.

Of course, it is important to avoid systemic reactions in every patient but perhaps more so in this particular type of patient. This is best done by attention to the local reactions from the preceding doses, by the gradual and easy stages of progression of doses and by care used in ascertaining that the needle is not in a blood vessel.

INDIAN OR KARAYA GUM

To the Editor:—Please give me any available information on the use of Indian gum (Karaya gum), in foodstuffs, toilet preparations and dental powders and pastes. I have found several patients sensitized to Indian gum. Most of them had violent perennial hay fever symptoms, the source of the Indian gum being wave sets. However, I understand that Indian gum is frequently used as a filler for ice creams and certain pies. One of my patients had a violent nasal reaction from swallowing a small amount of Indian gum. Consequently it can apparently cause trouble by being swallowed as well as by inhalation. In particular, I should like further information as to its presence in foodstuffs and also as to its presence in tooth powders and tooth pastes.

M.D., Ohio.

ANSWER.—Manufacturers are permitted to use such vegetable gums, if of suitable purity, as long as such use does not result in the concealment of damage or inferiority of the product, and provided their presence is conspicuously declared on the labels of foods in which they are not recognized ingredients. Karaya gum, depending on its source, may have either adhesive properties or a high hydrophilic property. Because of either of these characteristics, the gum has been used as a filler in the manufacture of ice cream and desserts. It is especially useful when there is need for preventing the product from losing its form as it melts. It has a further use in food products such as dessert powders and beverage bases, in which it is sometimes present in small amounts as an emulsifying agent. Its use as a mechanical laxative is increasing because of its low price and swelling properties.

It is a common ingredient of toilet preparations, denture adhesive powders and paste dentifrices. For the former it is

used principally in wave setting lotions because of its mucilaginous consistency. A case of alleged sensitivity to Karaya gum was reported by Samuel M. Feinberg in *THE JOURNAL*, Aug. 17, 1935, page 505. As a general rule, it does not occur in tooth powders. More often it occurs in tooth paste as a binding agent. It is being used for this purpose less frequently than formerly. Lactona Dentifrice, accepted by the Council on Dental Therapeutics of the American Dental Association, is the only one of the accepted dentifrices to contain it. There is not enough evidence at the present time to warrant the discontinuance of its use. Karaya gum is a common constituent of adhesive powders to hold dental plates. A report of the Council on Dental Therapeutics (*J. A. D. A.* 24:1383 [Aug.] 1937) indicates a connection with certain conditions such as tuberculosis, anemia and drowsiness, although the connection remains to be confirmed.

REMOVAL OF TEETH FOR PYORRHEA

To the Editor.—The question of the extraction of teeth because of pyorrhea has come up in the case of a young woman. I am unable to advise her because of the conflicting opinions of several dentists whom she has consulted about the matter. She is generally in good health except for a coxalgia, which is somewhat troublesome. The disorder at present is hardly severe enough to warrant the removal of her teeth, unless her present trouble might be considered the forerunner of a more severe type of arthritic disease. The first dentist whom she saw advised extraction of all the upper teeth and the fitting of a denture. He gave the following reasons for his advice: 1. That the treatment of pyorrhea is a protracted affair, with little if any promise of permanent cure, therefore making it more costly than a removable denture, which will be necessary sooner or later in any event. 2. That the depth of the pockets along the gum margin render it impossible really to get at all of the infection. 3. That to permit the diseased teeth to remain will result eventually in the eroding of the bony processes around the teeth, thus making the fitting of a removable denture more difficult later on. 4. That the teeth are cosmetically not good looking, because they are spaced far apart, are discolored and that for the latter reason a removable well fitted denture would be a distinct improvement cosmetically. 5. That there is a certain amount of danger in that these constitute foci of infection even though carefully looked after at regular intervals. Three other dentists insist that she should retain her own teeth as long as possible, that they can be successfully treated, and that there will be no danger of absorption of toxic or infective material if they are properly looked after. Since she has limited means, the financial part of the matter enters in. I have seen the x-ray films of the teeth, and the infective process extends half to three fourths of the way along all the roots of the upper teeth. Please give your opinion in this matter.

M.D., Minnesota.

ANSWER.—The first dental consultant gives five reasons for his opinion, which if correctly based on facts are sufficient to justify his advice. The other three consultants apparently give no reasons other than the statement that the teeth can be retained for a considerable period. This would seem to warrant acceptance of the first consultant's opinion. It is undoubtedly true that dentists often have been inclined to retain teeth as long as possible without sufficient consideration of more remote effects on the health and well-being of the patient. It is also true that physicians have been too ready to condemn teeth and advise extraction without sufficient consideration of the ultimate effect on the patient's denture and health.

More specifically, it is undoubtedly true that the treatment of such a condition would be protracted and, even if all the diseased tissue could be removed and the supporting tissue restored to a normal healthy condition, its maintenance would require eternal vigilance on the part of the patient and continued assistance on the part of a skillful dentist. The ultimate cost, therefore, would probably be greater than the placing of a denture. The depth of the pockets as indicated by the x-ray films undoubtedly makes it extremely difficult to remove all the infection and obtain restoration to normal in the supporting tissues. This is not, however, impossible. It is undoubtedly true that if the diseased condition of the teeth continues, or if it periodically recurs, there will be destruction of the alveolar bone that will make the placing of a satisfactory denture much more difficult. A complete cure will, of course, not improve the esthetic appearance and this may be sufficient reason alone to justify the removal of the teeth and their replacement by a denture. Undoubtedly there is "a certain amount of danger" to the patient's health and well-being if the infection and inflammation are not entirely cured and normal conditions maintained. Considerable emphasis should be placed on this. It is by no means certain, however, that the complete cure of the mouth will relieve the coxalgia. The pyorrhea may be related to this and may not be. In this connection it might be interesting to refer to the article by Dr. George H. Thiele on coccygodynia and pain in the superior gluteal region and down the back of the thigh (*THE JOURNAL*, Oct. 16, 1937, p. 1271).

IODIZED POPPYSEED OIL IN BRONCHIECTASIS

To the Editor.—1. What is the present status of lipiodol in the treatment of bronchiectasis? 2. How often is the treatment given? 3. How long does the lipiodol remain in the bronchioles before being absorbed? 4. Isn't there such a thing as a sensitivity to lipiodol, an allergy developed after a few injections? If so, what are the particular symptoms that manifest themselves?

M.D., Louisiana.

ANSWER.—1. During the last six years, much has been written regarding the therapeutic use of iodized oil in patients with bronchiectasis and asthma. The reports have varied from the remarkably optimistic view (Anderson, William: *New York State J. Med.* 36:1151 [Aug. 15] 1936) to complete denial of any value (Crip, L. H., and Hampsey, J. W.: *J. Allergy* 9:23 [Nov.] 1937). An excellent review of the literature is given in the paper by Crip and Hampsey. Included in their records is the result of a questionnaire forwarded to 335 selected specialists who are members of allergy societies, of the American Bronchoscopic Association and of the Triological Society. Of 230 members who replied, sixty-four had experience with this form of treatment. Only one third of these were still using it for the most part as an adjunct to medical management. Little enthusiasm was displayed for this procedure by most of those who were still using it. Crip and Hampsey report the results of treatment in forty cases, only four of which showed temporary improvement. They conclude that iodized oil is of questionable value for patients with asthma.

2. Treatment is usually given on one side at a time, usually once a week or less, often depending on the condition of the patient. As many as forty treatments were given in the series quoted.

3. The amount of material absorbed from the lungs is negligible. Most of it is coughed up and expectorated or swallowed. The material may remain in the lungs as long as three or four years.

4. Sensitivity to lipiodol is not likely to develop with repeated insufflations because of the negligible amount absorbed. If symptoms of hypersensitivity occur, they will be present after the first treatment. These may be of an allergic nature either to iodine or to poppyseed oil. They consist of fever, urticaria, arthritis, asthma and occasionally acute asphyxia. At least one fatal case of iododerma has been reported (Goldstein, D. W.: *Fatal Iododerma Following Injection of Iodized Oil for Pulmonary Diagnosis*, *THE JOURNAL*, May 9, 1936, p. 1659). Other untoward reactions reported are exhaustion from convulsive coughing, acute collapse of the lung, lipid or infectious pneumonia, traumatic bronchiectasis because of rupture of the terminal bronchioles from coughing, and pulmonary fibrosis and circulatory failure. The danger from the use of iodized oil in some patients with pulmonary tuberculosis has been indicated in a report by the Council on Pharmacy and Chemistry (*Dangers of the Injection of Iodized Oils*, *THE JOURNAL*, Dec. 3, 1932, p. 1946).

TREATMENT OF ECLAMPSIA

To the Editor.—What are the relative values of 50 per cent dextrose and magnesium sulfate solutions intravenously in eclampsia coming on three hours after delivery? Will you give me a brief outline of treatment for eclamptic convulsions in a patient never seen until in labor, with blood pressure 150 systolic, 92 diastolic, and slight edema of the ankles, convulsions occurring three hours after delivery?

M.D., Pennsylvania.

ANSWER.—While both dextrose and magnesium sulfate are administered in cases of eclampsia for the control of convulsions, the reasons for their use are not the same. Dextrose is given on the ground that there is a glycogen deficiency in women who have toxemias of pregnancy. Paul Titus believes that an insufficient carbohydrate intake in the maternal diet plus the sudden and extraordinary demands of fetal and placental growth and uterine hypertrophy bring about a glycogen deficiency in the body tissues, especially noticeable in the liver. The administration of dextrose in various concentrations is of distinct benefit in cases of preeclampsia and eclampsia.

Magnesium sulfate is given to patients with eclampsia on the ground that it controls convulsions, reduces edema and promotes diuresis, thereby eliminating the "toxins" of the toxemias. Many reports have appeared praising magnesium sulfate in the treatment of eclampsia. One of the most recent ones is by Stroganoff (*J. Obst. & Gynec. Brit. Emp.* 44:289 [April] 1937), who has done much to popularize the conservative treatment of eclampsia.

The treatment of postpartum eclampsia is as follows: The patient should be placed in a quiet and darkened room preferably in a hospital. A nurse or other attendant should be present constantly to see that the patient does not injure herself either

by biting her tongue, falling out of bed, aspirating vomitus or sometimes drowning from excessive pulmonary secretions. A clothespin covered with cloth will serve admirably as a mouth gag and should be placed near the patient's head. A tracheal catheter should also be close by so that mucus may be aspirated when necessary. The blood pressure should be recorded every hour and the pulse and respiratory rate counted at frequent intervals until improvement is observed. It is also important to measure the output of urine; this is best accomplished by keeping a catheter in the bladder.

As Dieckmann suggests (*Am. J. Obst. & Gynec.* 33:165 [Jan.] 1937), to control the convulsions it is best to use a combination of drugs at the same time because it might be dangerous to give enough of one drug at a time. One-fourth grain (0.016 Gm.) of morphine is given as soon after the first convulsion as possible. This is repeated every hour until the convulsions are controlled or until the respirations drop to ten per minute. In addition, 10 cc. of a 25 per cent solution of magnesium sulfate is given intramuscularly and 5 cc. of this solution is given after each convulsion or until 30 cc. has been administered. Another useful drug is soluble phenobarbital, of which 0.3 Gm. (5 grains) should be injected subcutaneously and repeated if necessary in twelve or twenty-four hours. Still another drug which has proved helpful is chloral hydrate. Two Gm. (30 grains) is given in 100 cc. of starch water (one tablespoonful of starch to 100 cc.) by rectum and repeated as necessary.

It is important to keep the lower bowel empty and this must usually be accomplished by means of enemas. If there is oliguria, anuria, coma, tachycardia or fever, hypertonic dextrose solutions should be administered intravenously. Every six to eight hours between 500 and 1,000 cc. of a 20 per cent solution should be given, each injection lasting from thirty to forty-five minutes. Sufficient dextrose solution should be given to insure a urinary output of at least 30 cc. per hour and this should be continued until normal diuresis begins. If 20 per cent dextrose does not produce diuresis, a 30 per cent solution should be used.

As soon as the patient becomes conscious enough to take and retain nourishment she should be given water, fruit juices and fruit. As improvement continues a more and more liberal diet is added.

RULES GOVERNING DISCLOSURE OF MEDICAL EXAMINATION TO INDUSTRIAL FIRMS

To the Editor.—What is the legal status regarding physical examinations which are made for industries and for employment application records? At the present time there appears to be a move on foot whereby various industries are requesting applicants for employment to have physical examination and complete health records. These records of the examinations made as well as of the history obtained is to be in duplicate, one of the records to be furnished to the industry in question. Some of these examinations are quite extensive. I have been wondering whether or not there might be a breach of professional secrecy as well as legal liability for the physician who enters into this sort of thing and furnishes all this information to the various firms in question. I should like to have an opinion on this point.

M.D., Pennsylvania.

ANSWER.—When a law undertakes to require a physician to report to a public officer or to an employer the results of examinations of employees who have been injured or who have contracted disease in the course of employment, the legal obligation to make the report carries with it the right to do so. To the extent to which the obligation to make such a report is modified by the circumstances incidental to the injury or disease, the right of the physician to make the report varies accordingly.

Aside from any legal obligation to make a report, with a correlative right to do so, the right of a physician to report to an employer the results of an examination of an employee or of an applicant for employment varies with the circumstances under which the examination is made.

If the examining physician is in the service of the employer and if the employee or applicant knows that fact, knows the purpose of the examination and knows that a report of the results of the examination will be submitted to the employer in the ordinary course of business unless timely objection is made, and if the employee or applicant nevertheless permits the examination to be made, the consent of the employee or applicant to the proposed report to the employer would doubtless be implied in the absence of an express understanding to the contrary.

If the physician is not in the service of the employer but is one selected by the employer or the applicant, no presumption of right on the part of the examining physician to disclose the results of the examination to the employer would be implied. Before making an examination under such circumstances, the examining physician should have a clear understanding with the applicant as to the nature and purpose of the examination

and as to the extent, if any, to which the examining physician is authorized by the examinee to disclose the results. If the examinee authorizes the physician to report to the employer the results of the examination, whether favorable or unfavorable to the examinee, the examinee should give written consent to the disclosure. No particular form of consent is necessary; the consent need be only such as indicates clearly an understanding on the part of the examinee and indicates his consent. Legally it is not necessary that the consent be in writing, but written consent will facilitate proof of the examining physician's right to make the disclosure, if any question arises later.

The safest and in some ways the most convenient procedure in all such cases is for the examining physician to give his report to the examinee himself or, if the examinee is a minor, to his parent or guardian, leaving it to the judgment of the examinee or his parent or guardian to submit the report to the employer or to refrain from doing so.

In any case in which a physician makes a report showing the results of his examination of any examinee, he should keep a copy of that report for future reference.

HONEY AND BEE VENOM IN ALLERGY

To the Editor.—Recently I have been approached concerning the value of honey for the relief of hay fever and other allergic conditions, especially those due to pollens. There have been short comments on its value in lay publications. Apparently only the honeycomb is of value. Is there any explanation for the mode of action, if any? What does the comb wax contain or hold in physical bond that could be of benefit? I understand that there is considerable formic acid in the finished comb and some in the honey itself. Would this acid be a factor? Is there anything in bee venom of value? STEWART R. JONES, M.D., Suttons Day, Mich.

ANSWER.—An analysis of American honey made by Browne of the U. S. Department of Agriculture showed that on the average it contained water 17.7 per cent, levulose 40.5 per cent, dextrose 34.02 per cent, sucrose 1.8 per cent, dextrans and gums 1.51 per cent, and ash (varying greatly from different sources) 0.15 per cent. Honey also contains several materials which vary greatly or are difficult to determine quantitatively, such as pollen grains, beeswax and some albuminoids which come either from pollen or from the honey itself. Free acid also is present and chemists have always considered it to be formic acid; but Browne states that it is largely malic acid, as the poison glands of bees do not produce formic acid. Various coloring materials of plant origin and enzymes also are found in honey.

A research of the literature shows no scientific study wherein the use of honey favorably influenced hay fever. On the other hand there are several notes of unfavorable effects. For example, Duke (Asthma, Hay Fever, Urticaria and Allied Manifestations of Allergy, St. Louis, C. V. Mosby Company, 1925, p. 215) states that patients sensitive to buckwheat may react to traces of buckwheat sometimes found in honey. Hansel (Allergy of the Nose and Paranasal Sinuses, St. Louis, C. V. Mosby Company, 1936, p. 343) states that patients with hay fever may be unable to tolerate honey because it frequently contains a great variety of pollens. Duke (*Arch. Int. Med.* 28:151 [Aug.] 1921) reported gastrointestinal allergy after the eating of honey. Walker (*J. M. Res.* 36:423 [July] 1917) reported asthma from honey, and Menagh (*THE JOURNAL*, March 3, 1928, p. 668) urticaria from the same source. Makai (*Deutsche med. Wchschr.* 48:257 [Feb. 23] 1922) fed honey to children who were receiving injections of horse serum and most had severe respiratory or gastrointestinal symptoms; control cases in which horse serum was not administered did not show effects from the honey.

Several articles on bee venom are in the literature. Haag and König (*Klin. Wchschr.* 15:1321 [Sept. 12] 1936) treated fifteen hay fever patients with injections of bee venom with good results in fourteen, eight of whom had no symptoms whatever. The injections were given subcutaneously, twice weekly, beginning with small doses with gradual increase. The treatments were given during the hay fever season and there were no reactions. Wolpe (*Wien. klin. Wchschr.* 50:1234 [Sept. 3] 1937; abstr. *THE JOURNAL* Oct. 23, 1937, p. 1409) gave injections of bee venom to a patient who had severe generalized urticaria after a bee sting; for five years no further attacks of urticaria occurred in this patient. An additional twenty-five patients with urticaria were treated with bee venom and fifteen were completely relieved and six others improved. He also treated six cases of angioneurotic edema (Quincke's disease) with bee venom with complete success. With the exception of the first patient, he does not state how long these patients remained well.

Tetsch and Wolff (Berlin letter, *THE JOURNAL*, Oct. 2, 1937, p. 1138) experimented with venoms and concluded that the active

substances are protein and that the composition of bee venom is similar to that of cobra and crotoalin venoms. Essex, Markowitz and Mann (*Am. J. Physiol.* 94:209 [July] 1930) experimented on dogs and concluded that bee venom has a physiologic action similar to that of histamine. This work agrees with that of Benson and Semenov (*J. Allergy* 1:105 [Jan.] 1930), who also showed that bee venom and histamine act similarly; they also demonstrated that allergy to bee stings is entirely comparable to allergy from other protein substances. The authors state that formic acid has never been demonstrated in bee venom, that Langer attributes the poisonous action of venom to a non-volatile, protein-free organic base, that Arthus and Lyssy believe that bee venom is a proteotoxin and that Flury concludes that Langer's protein-free constituent is not a simple base but a complex one, from which Flury isolated (1) an indole derivative, probably tryptophan, (2) cholin, (3) glycerin, (4) phosphoric acid, (5) palmitic and other fatty acids, and (6) a non-nitrogenous constituent having a saponin-like action. This last derivative contains the pharmacologically active principle of bee venom.

POSSIBLE ALLERGY TO HEAT

To the Editor:—A married woman, aged 25, has been under my observation for the past year because of intense itching of the skin of the whole body. The attacks are precipitated by an unusual amount of exercise, such as sweeping, washing clothes or running short distances. Excitement or higher temperatures of the air have the same result. She describes it as coming on whenever "her blood heats up." Relief can be obtained only by lying or sitting down and resting for a variable period. During an attack the skin is flushed and shows minute red spots of a darker color than the rest of the skin. There is no resemblance to an ordinary urticarial lesion. The spots fade rapidly with rest and leave no residue. Her past history is negative except for a normal pregnancy in 1930 and the family history is negative for allergy. She is perfectly normal and well developed and is in exceptionally good condition. She takes no medicine of any kind and the diet is well balanced and adequate. There is no complaint with regard to the gastro-intestinal tract except a very occasional mild attack of indigestion quickly relieved by alkalis. I have given her cutaneous tests for a large number of the common offenders in allergic disease with no positive results and have found that a change of environment has no effect. Sedatives had no result except that drug rash developed after the administration of phenobarbital. I would appreciate your comments and suggestions.

CHARLES A. ROSE, M.D., Almond, N. Y.

ANSWER:—Organic disease such as diabetes mellitus should be ruled out first. She should have a blood sugar estimation as well as urine examination. If organic disease can be excluded, the diagnosis of physical allergy (to heat) seems most likely. This could probably be confirmed by exposure of the patient to heat (hot bath, infra-red lamp, and so on). If pruritus follows, heat sensitivity is likely.

If heat seems to be the main factor, desensitization to heat should be tried. This can usually be done by gradually increasing the temperature of baths, beginning with tepid and progressing to hot baths, lasting perhaps twenty minutes, if the patient can tolerate this. Great care should be exercised not to increase the heat too rapidly. Other ways of application of heat can be tried instead of the baths, if desired, e. g., by increasing exposure to infra-red lamps.

ARTIFICIAL INSEMINATION

To the Editor:—Is artificial insemination considered practical in cases in which the husband has been found sterile? It would seem that desirable donors would be hard to find. Is there a reliable clinic or hospital which specializes in this work?

M.D., Missouri.

ANSWER:—Artificial insemination is an unpractical and dangerous procedure. Aside from the possibility of legal involvement as well as the possibility of blackmail there must not only be considered the possibility of gonorrhea (latent) and syphilis in the donor but also one must know definitely the entire family history of the donor as well as of his antecedents. Otherwise a tendency to insanity, epilepsy and other traits may be inherited by the offspring. Of course, tuberculosis must be excluded in the donor.

One must also take into consideration the diagnosis of sterility in the male. Most of the conditions causing absence of spermatozoa in a condom specimen can be relieved by either endocrine treatment or operation in case the tubes are occluded. The main factor is the diagnosis of the underlying condition.

Another factor to be taken into consideration is that artificial insemination whether from a stranger or from the husband himself is a serious procedure and not without considerable risk. There is no practical method of sterilizing the semen without killing the spermatozoa. Normally the genital secretions of the female seem to have the power to allow the spermatozoa to proceed upward and at the same time of keeping back bacteria from infecting the uterus and parts beyond. This must

be the case; otherwise infection would be frequent when it is considered that the act of intercourse is often undertaken without any aseptic precautions or even ordinary cleanliness. This preventive power of the genital secretions of the female is done away with in artificial insemination.

PAINFUL PARALYSIS AFTER ANTIRABIC TREATMENTS

To the Editor:—A white man, aged 43, 5 feet 10 inches (178 cm.) tall, weighing about 170 pounds (77 Kg.), took the antirabic treatment recommended by the North Carolina State Board of Health, consisting of twenty-one injections into the anterior abdominal wall. During the last seven injections he noticed a generalized paralysis of his extremities (not complete). This gave rise to severe pain in his extremities, so that he was confined to bed for six weeks. The pain has somewhat abated and the extremities regained some of their muscular activity. He has been treated by numerous physicians and has been given fever therapy and salicylates for the last three years. At present he complains of weakness, more severe in his left arm and leg, and of pain in all his muscles. The blood pressure is 120 systolic, 80 diastolic; and the blood count is normal. The urine is normal. The reflexes are normal on the right and hyperactive on the left. Please suggest treatment.

W. R. BEACH, M.D., Westfield, N. C.

ANSWER:—It is impossible to localize the process from the data submitted. No mention is made of any sensory abnormality or cranial nerve defect. One can guess that because of the pain and the generalized paresis of the extremities the case originally was a meningomyelitis with radicular involvement occurring with the fourteenth injection of antirabic material. It is not stated whether the substance used was vaccine; dead cord or other. Usually the patients who develop this unfortunate complication either die from two to three weeks after the onset of the cerebrospinal lesion or make an almost complete recovery within a year. If there is any improvement taking place, regardless of how little, the suggestion is made that watchful waiting and symptomatic supervision be the keynote of any treatment. If the pain is disturbing, one can consider either a chordotomy or section of a sufficient number of posterior roots to the affected extremity. Potassium iodide in the form of a saturated solution given in doses of 15 drops three times daily is suggested for trial. Large continued doses of vitamins B₁ and B₂ should be prescribed.

SODIUM HEXAMETAPHOSPHATE IN HYPERHIDROSIS AND SKIN DISEASES

To the Editor:—Please advise me as to the use of sodium hexametaphosphate in excessive sweating and certain skin conditions. Also tell me the strength preparation that is used and other details that might be useful.

M.D., Wisconsin.

ANSWER:—Sodium hexametaphosphate is a water softener yielding a slightly acid solution and possessing a strong buffer action. Applied to the skin, it tends to lessen perspiration and sebaceous secretion, drying the skin and counteracting the irritating effects of alkalis and oils (Jones, K. K.; Murray D. E., and Ivy, A. C.: Sodium Hexametaphosphate: Its Use for Certain Occupational Dermatoses, *Industrial Med.* 6:459 [Aug.] 1937).

For hyperhidrosis of the feet, washing with tincture of green soap was followed by rinsing in a 1 or 2 per cent solution of sodium hexametaphosphate in water, and a thin film of the powdered drug was dusted into the shoes each morning. Cotton socks were worn, changed daily. Prompt control of the sweating was the result, maintained as long as the use of the drug was continued.

For dermatitis from soap, a 1 per cent solution of sodium hexametaphosphate was used for washing, no soap being allowed. The patients were instructed to sponge with the sodium hexametaphosphate solution four times a day, in the morning, at noon, on ceasing work and before retiring. In spite of continuing their work in a soap factory, they showed improvement in a few days and the irritation, which had been present for from one to five months, had disappeared in a few weeks. As long as the treatment was continued, these patients had no recurrence of the dermatitis; but when the use of the hexametaphosphate was given up, the dermatitis returned. There was no bad effect on the skin except increased dryness.

For oil acne and oil dermatitis the drug also was effective, the redness and itching clearing up first, the acne yielding more slowly. As a prophylactic, sodium hexametaphosphate was effective.

For ringworm dermatitis of the feet, sodium hexametaphosphate was useful in relieving the itching and drying the skin but was not able to cure any but the mildest cases.

The conclusions of these authors were as follows: "1. Sodium hexametaphosphate acts on the skin to form a protective coat-

ing, acid in nature, that inhibits the action of alkali on the skin. 2. Sodium hexametaphosphate, either as a dry powder or as a solution, will reduce the excretion of invisible perspiration by 50 per cent. 3. The protective film of sodium hexametaphosphate on the skin removes the irritation of soap and oil and acts as a prophylactic and cure for this condition. 4. The protective film formed by the hexametaphosphate is useful in the treatment of patients having hyperhidrosis and trichophytid infestations." The last statement can be criticized. The word trichophytid was probably a misprint. Trichophyton was meant, no doubt.

Recently Dr. Jones reported that for hyperhidrosis stronger solutions, 25 or even 50 per cent, can be used without skin irritation, and with effect in resistant cases.

BILATERAL SCIATICA

To the Editor.—A patient worked for several years on a delivery truck, delivering bags of feed and barrels weighing from 100 to 400 pounds. About a year or eighteen months ago he developed a sciatic neuritis, first in one leg, then later in both legs, which became so severe that he was forced to stop his work and receive medication. He improved and was free from pain, but when he tries to do some work his pains return. The man's physical condition is perfect otherwise, the Wassermann reaction is negative, and the urine, blood and spine are normal. He is bringing suit for compensation. I was his physician. Was this condition caused by a continuous injury due to heavy lifting and striving?

M.D., New Jersey.

ANSWER.—This patient should have the advantage of orthopedic and neurologic consultation. Pain of this type, double sciatica, might be due to an arthritis of the spine or it might be due to some intraspinal lesion such as a cord tumor or a slipped intervertebral disk. Examination of the cerebrospinal fluid should be made to ascertain whether there is an excess of protein and, if so, an injection of iodized poppy-seed oil solution into the spinal canal would be justified to determine whether a filling defect would show in the roentgenogram. The accuracy of this method of diagnosis is remarkably high. If there is a defect present an exploration of the spinal cord would be indicated.

It would be difficult to connect this man's condition definitely with his occupation although it is reasonable to presume that it was at least a contributing factor.

BURNING TONGUE

To the Editor.—What is the cause and treatment for a burning sensation on the anterior third of the tongue, bilateral? There is nothing abnormal about the tongue and no dental disorder. All clinical tests are negative; blood pressure is normal. There are no eye or ear complaints and no other objective or subjective signs.

GEORGE H. JANTZEN, M.D., Long Island, N. Y.

ANSWER.—The sensory innervation of the anterior two thirds of the tongue is by way of the fifth nerves (trigeminal). The taste component for this area goes through the lingual branches to the chorda tympani connection between the fifth and the seventh nerves (facial) and thence to a common taste center.

The burning sensation (glossodynia) described is rare but distressing. It can have several possible causes but most typically is found in women beyond the age of 50 who have a low pain threshold, often associated with cancerphobia or other complaints of a functional order. It has also been ascribed to dyspepsia, gouty diathesis, faulty diet, nervous tension, and as reflex from regional infections such as a dental abscess. If it has an inflammatory local cause (rough teeth, dentures which are porous or chemically irritating) or a systemic cause (early pellagra, pernicious anemia) the local change should be obvious. An abnormal condition of gastric acidity, either hypo-acidity or hyperacidity, has been blamed for the sensation. A nerve tract involvement might be present but it is usually unilateral. A chronic lingual tonsillitis may be diagnosed by cocaineization of the nasal, sphenopalatine or Meckel's ganglion.

Recently two other causes have been described: About 10 per cent of a series of patients who had signs and symptoms from destruction and disturbed function of the temporomandibular joint had burning or prickling pain along the dorsal margin of the tongue produced reflexly by pressure of the condyle on the auriculotemporal nerve. Relief was often obtained by repositioning the lower jaw. The second cause is the electric current which is produced by the presence in fillings or dentures of metals of unlike potential. The associated symptoms and signs can include a metallic taste, acute dental nerve sensations and actual inflammation.

Since the burning in this case is bilateral, anterior, persistent and independent of a demonstrable pathologic condition, it could be psychogenic, reflex or due to a local diffuse cause. If, after

reviewing the suggested causes and testing the gastric acidity, the taste sensation of the entire tongue, and so on, there then seems to be no correlation, one could tentatively treat with psychotherapy while observing further. Hydrochloric acid or alkalis, electrical stimulation, amniotin, attempts to improve the general health and reduce the strain, and reassurance have all been used empirically but the success has been only partial.

DESENSITIZATION TO HOUSE DUST

To the Editor.—I have under my care a woman who is sensitive, among other things, to house dust. Is it possible to desensitize the patient with a preparation of her own house dust?

M.D., Ind.

ANSWER.—It is not only possible but highly desirable to treat such a patient with house dust extract. The dust is collected from the home, preferably with a vacuum cleaner. If one is to obtain a potent preparation, great care must be taken to collect the dust from mattresses, pillows and furniture. This is accomplished by using an attachment on the vacuum cleaner. Usually an insufficient amount of dust is collected in this manner. It is therefore frequently necessary to add to that dust the dust obtained by sweeping the carpet.

To 20 Gm. of such dust, ether is added and allowed to stand for a few hours. The ether is then removed and the dust subjected to another extraction with ether. After the second quantity of ether is drained off the dust is thoroughly dried and extracted with 100 cc. of Coca's solution for twenty-four hours. It is filtered through filter paper and finally through a Seitz filter. It is then tested for sterility.

Usually after several injections, beginning with small amounts of this extract, the patient shows clinical improvement. A sufficient degree of desensitization can be accomplished with good clinical results but it is doubtful whether complete desensitization can ever be obtained.

PAIN IN AURICULAR NERVE

To the Editor.—A woman, aged 37, complains of a sharp stabbing pain, intermittent in timing and lasting from a minute to a minute and a half, with a total duration of from a few minutes to two or three hours. This pain has existed three years and starts about 2 cm. above and 2 cm. to the right of the suprasternal notch. It radiates over the distribution of the superficial cervical nerve and then up the great auricular nerve in front and superior to the ear. There are no areas of hyperesthesia or areas that would serve as trigger zones. The only thing that she has taken for relief is acetylsalicylic acid repeated every three hours for three or four doses. This gave very little relief and the pain gradually subsided. Physical examination and roentgenograms are negative. I would like some suggestion on diagnosis and treatment.

M.D., Idaho.

ANSWER.—Judging from the history of the location and nature of the pain, the patient may have arthritis involving the upper cervical region of the spine, as the great auricular nerve is a branch of the upper cervical nerve. In the way of treatment, an extension of the spine might be tried, which sometimes relieves pain, and light therapy would be helpful applied to the upper cervical region of the spine. There are no objections to her continuing the acetylsalicylic acid. Sometimes an alcohol injection of the nerve, if properly done, will give relief.

ORALSULIN

To the Editor.—Has "Oralsulin," used as an insulin given by mouth and sold by the Lafayette Chemical Company, Indiana, any value in diabetes mellitus?

M.D., Michigan.

ANSWER.—No oral insulin of Lafayette Pharmacal, Inc., has been accepted by the Council on Pharmacy and Chemistry, nor has Lafayette Pharmacal, Inc., requested consideration of the product by the Council.

Over eleven years ago, THE JOURNAL in discussing "Enterocap Oralsulin" (Dec. 4, 1926, p. 1935), pointed out the lack of evidence for the efficiency of orally administered preparations of insulin and pancreas. In a concluding paragraph appeared the following statements:

"In commenting editorially on the administration of insulin, THE JOURNAL as long ago as 1923 called attention to the desirability of giving wide publicity to the current limitations of this most promising therapy, since many 'just-as-good' pancreatic and antidiabetic preparations for oral use were already being put on the market. This warning is still in order, for there is yet no convincing evidence to show that any preparation taken by mouth is an effective means of producing the characteristic action of insulin."

No new evidence has been found to necessitate a revision of the statement published at that time. Recently the federal authorities charged with the enforcement of the Food and Drugs Act seized a shipment of Enterocap Oralsulin and declared the

product adulterated and misbranded. According to the government report, examination showed that the preparation contained no insulin and that the labeling bore false and fraudulent representations regarding the curative or therapeutic effects of the product (Notice of Judgment 27373, Food and Drug Administration, U. S. Department of Agriculture, issued December 1937). No products of Lafayette Pharmacal, Inc., stand accepted by the Council on Pharmacy and Chemistry.

PECTIN IN OSTEOMYELITIS

To the Editor:—Please give me information on the use of fruit pectin in the treatment of osteomyelitis. E. M. GULLATT, M.D., Ada, Okla.

ANSWER.—A report on the bactericidal action of pectin was published by Haynes, Tompkins, Washburn and Winters in the *Proceedings of the Society for Experimental Biology and Medicine* 36:389 (June) 1937. Comment regarding this preliminary report appeared in *THE JOURNAL*, Oct. 14, 1937, page 1283. The report stated that 2 per cent commercial pectin added to heart-infusion broth would kill *Escherichia coli* within twenty-four hours, while control cultures adjusted to the same pH showed a thousandfold increase in bacterial count. It should be emphasized, however, that this in vitro bactericidal property is dependent on the acidity of the pectin broth mixture and is not apparent in neutral or alkaline mediums. The report also describes the successful results of the treatment of open wounds with pectin solution. It is too early, however, to evaluate this work, which has not yet been confirmed by other investigators.

SEA TANGLE TENTS

To the Editor:—I am enclosing a box cover and two so-called sea tangle tents, which were purchased at a local drug store on the recommendation of a midwife, to be used in the performance of an abortion by her. The midwife is now under arrest and the local authorities have asked me to write you to find out whether or not there is any legitimate use of these tents at any time. M.D., Pennsylvania.

ANSWER.—As far as is known not a single American obstetrician of good repute uses tents in his practice at the present time. Many years ago, however, tents were occasionally used to produce softening and dilatation of the cervix in cases of therapeutic abortion. Today no mention is made of tents in any American textbook on obstetrics or in medical literature. However, British obstetricians recommend tents for terminating pregnancy. In the Queen Charlotte's Textbook of Obstetrics, edition 4, page 478, appears the following statement. "The simplest method of terminating pregnancy, during the first twelve weeks, is by inserting a laminaria or sea-tangle tent into the cervical canal. Tents are sterilized by immersion in absolute alcohol for at least forty-eight hours. . . . Tents act by absorbing water, which causes them to swell considerably. . . . Sepsis is a danger."

INTRASPINAL INJECTION OF SOLUTION OF VITAMIN B₁ HYDROCHLORIDE FOR MULTIPLE SCLEROSIS

To the Editor:—A patient with multiple sclerosis for about fifteen years has received treatment in various hospitals and clinics without benefit. This patient has recently become interested in newspaper reports of the work of Dr. Elias Stern of New York on the use of vitamin B₁ in multiple sclerosis. I have been unable to obtain any authentic information on this work and would appreciate learning whether it is of real value in multiple sclerosis and, if so, the plan of treatment.

M.D., Pennsylvania.

ANSWER.—There is no convincing evidence that the injection of thiamin chloride directly into the spinal canal is of any more value in multiple sclerosis than the injection of thiamin chloride into the blood stream or indeed intramuscularly. On the other hand, it is certain that intraspinal injection of thiamin chloride is not without danger, and there is knowledge of at least one fatal result from this treatment.

CAR SICKNESS IN CHILDREN

To the Editor:—Please offer suggestions as to the treatment of car sickness in children. M.D., Minnesota.

ANSWER.—Car sickness is similar to sea sickness but is caused by the motion of a land-propelled vehicle. If the child were not taken in moving vehicles, the condition would not occur. When it is necessary to transport a child who suffers from car sickness, it might be helpful to administer a sedative such as one of the bromides in a small dose, in an attempt to mitigate the condition. Both car and sea sickness are probably types of vertigo of vestibular origin.

NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Examinations of the *National Board of Medical Examiners and Special Boards* were published in *THE JOURNAL*, May 21, page 1776.

Washington January Examination

Mr. Dave S. Cohn, secretary, Department of Licenses, reports the examination held by the Washington State Medical Board at Seattle, Jan. 19, 1938. The examination covered 7 subjects and included 70 questions. Thirteen candidates were examined, all of whom passed. Thirteen physicians were licensed by reciprocity and four physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1935)	85.7, (1937)	87.1

Book Notices

A Text-Book of Ophthalmic Operations. By Harold Grimsdale, M.D., F.R.C.S., Consulting Ophthalmic Surgeon to St. George's Hospital, and Elmore Brewerton, F.R.C.S., Consulting Ophthalmic Surgeon to the Metropolitan Hospital. Third edition. Cloth. Price, \$6. Pp. 322, with 165 illustrations. Baltimore: William Wood & Company, 1937.

Eighteen years has elapsed since the publication of the second edition of this English textbook on ophthalmic surgery. The authors state that they "have in the past dealt too much with historical operations." In the present edition they have excised much that had "interest only in the development of operative surgery, and have tried, by leaving out unessential matter, to make a book more helpful to the student of ophthalmology." The object of the work is "to give the student, in outline, the chief ways in which the various problems have been attacked, and to leave him to adapt some one of them to his varying requirements." To this end they have adhered to their original classification of operations and have added a section on the surgery of retinal detachment.

The section on muscle surgery is rather inadequate. The indications for the various procedures are not clear and many antiquated operations have been retained, with the omission of many American adaptations of the various procedures. The use of the O'Connor cinch operation is not mentioned as useful in the surgical treatment of the phorias. The Wheeler operation on the oblique muscles is omitted and the Himmelsheim transplantation technic in the surgery of paralytic strabismus is not considered. The illustrations of the various muscle procedures are not particularly illuminating; especially is this true in the section on ptosis operations. The Blascovics operation is not mentioned. Many other procedures described since 1933 are omitted. In the section on lid surgery many infrequently used operations are described in detail with the omission of recently described procedures. The illustrations here also are difficult to follow and the indications not clear. Wheeler's tarsorrhaphy operation and the plastic procedures of Imre are not considered. The surgical treatment of chalazia is given nine lines and the surgery of tumors of the lids and conjunctiva is omitted. The descriptions of enucleation operations and substitutes are well done, as is the section on the lacrimal apparatus.

The chapters on intra-ocular surgery are far superior to the previous chapters. The descriptions of cataract and after-cataract surgery are clear, concise and conservative. The section on glaucoma gives a rather complete description of procedures; however, in discussing the mode of action of cyclodialysis, the authors state, after raising various questions, that "these questions must remain unanswered, except theoretically, since there are no records, to our knowledge, of any anatomical examinations." They have overlooked that both Elschnig and Kronfeld have examined and reported on microscopic sections of eyes enucleated some time after a successful cyclodialysis had been done. The treatment of complications following intra-ocular surgery is not considered by the authors. The closing chapters on surgery of the cornea and sclera are well considered, although Wiener's corneal stripping operation is omitted. The chapter on foreign bodies in the eye is good. Each chapter is preceded by a short anatomic review, which serves as an excellent foundation for the surgical anatomy of the operation to follow. The sections include a short bibliography so that original descriptions may be consulted. The text and bibliography are complete. The technic is conservative. It is a commendable work for both students and ophthalmologists alike. A comprehensive index completes the work, which from the bookmaking standpoint is good.

Die Brotnahrung des deutschen Volkes und seines Heeres in der Wirkung ihrer Eiweiße auf die Energetik des Zwischenstoffwechsels. Von Adolf Bickel, Professor der pathologischen Physiologie an der Friedrich-Wilhelms-Universität in Berlin. Paper. Price, 2.20 marks. Pp. 64. Leipzig: Georg Thieme, 1937.

The author has summarized the results of experimental studies performed in his laboratory on the nutritional value of the proteins of rye and white bread. A new technic for the study of the nutritional quality of protein was developed. Groups of male rats, each animal weighing about 200 Gm., were fed the bread or other material studied for comparison, and small amounts of a complete salt mixture, orange or lemon juice and cod liver oil. The diets were adjusted by adding small amounts of sugar, so that the nitrogen content of each food mixture was essentially identical. When rye bread and white bread were thus studied, it was found that the nitrogen balances were approximately the same (slightly positive). Animals fed 100 per cent rye bread showed the highest fecal nitrogen and the lowest urinary nitrogen. They also showed the highest ratio of carbon to nitrogen in the urine and the highest Vakut-O:N ratio (the amount of oxygen necessary to oxidize the organic substances in the urine divided by urinary nitrogen). Animals fed on bread made from mixtures of white and rye flours showed intermediate values. The author states his belief that the results indicate that the protein of rye bread has high nutritive value and that this may be due in part to the effect which it produces on the intermediary metabolism.

Love and Happiness: Intimate Problems of the Modern Woman by I. M. Hotep, M.D. With a prefatory note by Dr. Logan Clendening. Cloth. Price, \$2. Pp. 235. New York & London: Alfred A. Knopf, 1938.

Dr. Logan Clendening in this book turns philosopher on the topic of women—a dangerous subject on which to philosophize for either a doctor or a philosopher. The book is written in his best mood and seems to be based on his service as father confessor to a great many inquiring damsels. He recognizes the fact that there is at this time a highly developed interest in this subject and the need for instruction. Times have changed! The new freedom for women, the coming of the motor car, the removal of the home as the center of family life, have forced many young persons to the textbooks or to the vague and fantastic information distributed in the gutter or in the club. It is important to have a book written by a physician of long experience who knows the world and its ways from the outside rather than from the laboratory, and who can write not only so that all who read may understand but also so that all will want to read. This book merits a wide circulation.

Injectons continues intravasculaires en physiologie et en thérapeutique. Application au traitement des états de choc par l'adrénaline. Par le Docteur Jean Sallet. Paper. Pp. 260, with 5 illustrations. Paris: Librairie E. Le François, 1936.

The brochure deals with the prolonged intravenous injection of epinephrine from an experimental as well as a clinical standpoint. The author points out that these injections are dangerous unless they are accurately timed and dosed. Thus, for instance, doses of from 0.001 to 0.005 Gm. per kilogram per hour cause a sinking of the blood pressure by as much as 10 to 20 mm. of mercury during the duration of the injection. Doses of 0.008 Gm. per kilogram per hour, on the other hand, produce a rise in pressure. The threshold lies somewhere between 0.006 and 0.008 Gm. per kilogram. With this fact in mind, it is easy to appreciate the importance of an accurately timed infusion instrument, and such a one the author finds in the transfusion apparatus of Henry and Jouvet. While the quantity of epinephrine solution used is likely to vary, the most commonly employed strength is 1 cc. of the solution of epinephrine (1:1,000) in 100 cc. of physiologic solution of sodium chloride, yielding a dilution of 1:100,000. One of the most important features is regulability of speed of injection, which may have to vary from 10 cc. to several liters per hour. The optimal speed seems in general to be 1 cc. per minute. Such injections are capable of producing a rise in blood pressure, which however is followed by a fall after the discontinuance of the injection. The author also observed a diminution in urinary and bile secretion, a marked contraction of the spleen,

especially in a condition of splenomegaly, resulting in a considerable increase of red and white blood corpuscles in the circulation. He has observed twice among fifteen cases a considerable diminution in the resistance of the red corpuscles during the continued injection of the epinephrine. Hyperglycemia is produced more readily than is rise in arterial pressure, and both are more easily produced in the human being than in the anesthetized dog. By injection in the mesenteric vein of dogs, the author was able to demonstrate considerable destruction of epinephrine by the liver. Good therapeutic results have been secured in six of nine cases of surgical shock and in two cases of obstetric shock. The injections are in general well tolerated, except that sometimes headache or palpitation is complained of. It is necessary, however, to keep the pulse, respiration and blood pressure under constant supervision. While the method requires delicate technic and constant supervision, it may be life saving in the therapy of shock.

Treatment of Some Chronic and 'Incurable' Diseases. By A. T. Todd, O.B.E., M.B., M.R.C.P., Honorary Physician, Bristol Royal Infirmary. Cloth. Price, \$3. Pp. 203. Baltimore: William Wood & Company, 1937.

The adjectives employed in the title are intended to suggest that the current therapy for these conditions is either unsatisfactory or completely ineffective. Important causes of our ineptitude of therapeutics, the author contends, are the anatomic designations of and outlook on diseases and the struggle for the unification of etiology. Anatomic localizations are correct for traumas but do not help the progress of the therapy of disease, especially chronic disease. One should not say of a patient that he has a disease of the joints but rather "this sick person has maximal symptoms in his joints." The attempt at the unification of etiology is equally obstructive to progress. There are two dicta in etiology which deter therapeutic progress: (1) the like cause, the like effect; (2) all symptoms must be referable to one etiologic event. These are unutterably stupid. The like cause, a wetting, may induce pneumonia in one man and kill him; may occasion chronic rheumatism in another and cripple him; may reduce the temperature of another with typhoid and save his life. That all symptoms must be attributed to one lesion does not hold in chronic conditions, for lesions are usually multiple. The same cause must produce different effects, depending on those subsidiary and little known dysfunctions which make up what used to be called diathesis. How unorthodox the author is may be gathered from these quotations from his chapter on diabetes mellitus:

Insulin is not essential for the utilization of carbohydrate.

"Insulin should not be used in the routine treatment of diabetes," for if insulin is administered regularly to normal men or animals and then discontinued, diabetes develops and lasts for days or weeks. This can be interpreted only as injected insulin having suppressed autogenous production.

It is not my object to claim that insulin has no value in the therapy of diabetes; almost every case of diabetes in my clinic is given insulin during the early stages of treatment, but weaning from insulin is attempted at the earliest possible stage. For the comatose stages insulin is absolutely essential if life is to be saved.

Writers on diabetes mostly condemn synthalin out of hand as a dangerous remedy; very few mention it with any favor. It is true that synthalin can be dangerous if administered in too large a dosage, or conjoined with an unsuitable diet; properly administered, however, it is superior to insulin in most cases, as injection is not necessary, and the chance of cure is much greater than is the case with insulin. As adjuncts to synthalin therapy bile salts should be administered daily, and patients are advised to replace a meat ration by sweetbreads once or twice weekly. Patients are also advised to replace one meat ration each week with liver, cooked according to taste.

There is hardly a chapter in this book that does not upset one's textbook notions of the subject with which it deals. There is hardly one of them from epilepsy, false phthisis, asthma and hay fever, postencephalitic parkinsonism, exophthalmic and toxic goiter, parenchymatous nephritis, duodenitis and hepatic defect, false heart disease, constipation, acute rheumatism, chorea, ulcerative colitis or chronic rheumatism to cancer that does not contain some original ideas advanced by the author. Even if only 10 per cent of the unusual therapeutic suggestions contained in this book are as claimed, the book would be worth many times its weight in gold to every physician. One cannot help wishing that the author's vision and imagination might be tempered by a more critical and scientific attitude. Neverthe-

less, if one has the misfortune of suffering from a chronic or "incurable" disease, one could hardly have a better fate than to be treated by so optimistic and enterprising a therapist as Dr. A. T. Todd.

Normale und pathologische Physiologie der Bewegungsvorgänge im gesamten Verdauungskanal. Von Prof. Dr. med. Werner Catel, Direktor der Universitäts-Kinderklinik und -Poliklinik, Leipzig. Teil 1: Methodik, Anatomie, normale Physiologie. Paper. Price, 11.50 marks. Pp. 250, with 87 illustrations. Leipzig: Georg Thieme, 1936.

This volume sets as its goal the explanation of the normal and pathologic physiology of the entire gastrointestinal tract. It begins with a consideration of the act of mastication and in turn takes up each muscular process in each part of the gastrointestinal tract. No attempt is made to explain the secretions of the tract. Any suitable method is used, although chief emphasis is laid on roentgenographic and kymographic records. Animal experiments are occasionally cited. In addition case records taken from the files of the author are used to illustrate particular points. This volume differs from the majority of similar textbooks in that considerable space is allotted to problems arising in pediatrics. This undoubtedly reflects the position of the author, as indicated in his rank. As a textbook for practitioners and students the volume will serve as a useful aid. The statements as a whole are accurate and take advanced attitudes toward the problems encountered in gastrointestinal work. Only in a few places such as in the discussion of congenital pyloric stenosis does the author allow himself to digress into a detailed discussion. Usually the points made are direct, although adequate explanation of phenomena is offered. The pharmacologic section comprises about forty pages of the text, so that only bare statements relative to the action of the leading drugs are presented. The numerous illustrations help to drive points home.

A Practice of Orthopaedic Surgery. By T. P. McMurray, M.B., M.Ch., F.R.C.S., Director of Orthopaedic Studies and Lecturer in Orthopaedic Surgery, Liverpool University. Cloth. Price, \$5. Pp. 471, with 178 illustrations. Baltimore: William Wood & Company, 1937.

This book was written by a man of excellent training and background, having inherited from Sir Robert Jones, who in turn followed Hugh Owen Thomas, the famous Orthopaedic Shrine at 11 Nelson Street in Liverpool. The author gives his preferences rather dogmatically, which is commendable. He has avoided giving details of many operative procedures which are usually confusing. Instead, he has given the methods which he has found most satisfactory in the largest number of cases. There are fine chapters on disabilities and derangements of the knee joint. There is an excellent chapter on splints and apparatus. The chapter on adhesions and ankylosis crystallizes the teachings of Sir Robert Jones. There is an interesting reference to the Baldwin operation for ankylosis of the inferior radioulnar joint. The chapters on tuberculosis are brief but satisfactory. A good description of osteoarthritis of the knee includes the author's favorite oblique osteotomy.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., M.D. Volume V: Endoscopy of Respiratory Tract to Goitre. Cloth. Price, \$12. Pp. 683, with 145 illustrations. London & Toronto: Butterworth & Co., Ltd., 1937.

From endoscopy through goiter marks the progress of the fifth volume of the British Encyclopaedia of Medical Practice. Among the leading subjects are epilepsy, eruptions, the eye, food and the gallbladder. Special interest attaches to a fine article on etiquette and ethics in medical practice and to deformities and diseases of the foot. This volume, like the others in this series, is handsomely published and profusely illustrated and represents essentially a series of short monographs, written from the British point of view. The fact that the British pharmacopeia is the basis of all therapeutic discussions tends to diminish somewhat the value of the work for the American reader. The discussion on epilepsy is by the well known British neurologist W. Russell Brain (rather strange that two of the greatest neurologists should have been named Brain and Head). Notwithstanding the up-to-date character of the book, it contains no reference to the study of the brain in epilepsy by encephalography. This article seems to be essentially a routine

discussion of the subject without much that is stimulating or new. Especially interesting in this book is the section on gassing and poison gases in war. This is a subject which is today concerning the British medical profession far beyond the degree of interest aroused previously. This article, which is written by Lieut. Col. L. T. Poole of the Royal Army Medical College, is one of the most succinct and complete discussions of this kind yet made available to the general reader.

Textbook of Gastroscopy. By Norbert Henning, Professor of Medicine in the Municipal Hospital, Fürth. Translated by Harold W. Rodgers, F.R.C.S., St. Bartholomew's Hospital, London. Cloth. Price, \$2.75. Pp. 86, with 33 illustrations. New York & London: Oxford University Press, 1937.

The German edition of Henning's textbook was reviewed in THE JOURNAL Dec. 28, 1935. Rodgers' translation is excellent. Unfortunately he has not changed such passages as are now obsolete; e. g., the recommendation of the rubber sponge, a device which in the meantime has proved to be dangerous. However, the small volume will be welcome to internists and surgeons who want to acquaint themselves with the sudden development of a method which seems to have become an important asset to the medical armamentarium. The gastroenterologist and the gastroscopist will be in need of one of the more detailed textbooks on this subject. Rodgers, in his preface, describes the rapid development of gastroscopy in an amusing way. "With the invention of the flexible gastroscope there came an awakening in gastric disease, and the German clinics have had visitors from all parts of the world go to them for their first step in gastroscopy. The English invasion began toward the end of 1934, and since then several young surgeons and fewer young physicians have, ignoring Lord Horder's pronouncement that gastroscopy was repugnant to the English character [sic], traveled to Leipzig . . . and have come back with knowledge, enthusiasm, and some, maybe, have even smuggled the conveniently flexible instrument through the customs strapped to their legs and hidden by their trousers." This, indeed, is history of medicine. However, the young American physician, traveling through Europe, should be warned to consider the custom officials of New York to be smarter than those of London. Rodgers also states in his preface that he has never met a gastroscopist who has had the instrument passed on himself. This experience is not shared by the reviewer.

Muir & Ritchie's Manual of Bacteriology. Revised by Carl H. Brown, M.D., LL.D., D.P.H., Gardner Professor of Bacteriology, University of Glasgow, and Thomas J. Mackie, M.D., D.P.H., Irvine Professor of Bacteriology, University of Edinburgh. Tenth edition. Cloth. Price, \$7.25. Pp. 996, with 218 illustrations. New York & London: Oxford University Press, 1937.

The original publication of this book occurred in 1897. Sir Robert Muir has withdrawn from participation in this revision so that the original authorship has now come to an end. This edition has been added to especially in the chapters on filtrable viruses. The nomenclature is out of date and is not in keeping with present accepted views. The physiologic and immunologic portions are rather superficially handled. There are numerous omissions of important work during the past five or six years in many of the fields. The plan of putting the colored plates in the front and all the bibliography in the back of the book is an awkward arrangement. The book leaves the impression of being superficial and skimming over a large amount of material without a serious consideration of any one subject.

How to Feed Young Children in the Home. By Mary E. Sweeney and Dorothy Curtis Buck. Paper. Gratts. Pp. 68, with illustrations. Detroit: The Merrill-Palmer School, 1937.

This is a brief review of the values in ordinary foods, sufficiently comprehensive for the use of the mother in the home, plus some good advice about children's diets, and many excellent recipes for dishes suitable for feeding children. It is published under theegis of the well known Merrill-Palmer School, Detroit, with the aid of a grant from the Irradiated Evaporated Milk Institute. There is a heavy emphasis in the recipes on irradiated evaporated milk. While there is no overt suggestion that bottled fresh milk is inferior, that impression is subtly conveyed. Otherwise there is no objection to the booklet, which should prove useful, especially to those mothers who must rely

on free educational material. Since the sponsorship of the irradiated evaporated milk interests are definitely and openly stated in the booklet, it can be weighed on its own merits with full knowledge of its source. This is a fundamental requirement for educational acceptability of material from commercial sources or developed with commercial aid.

Modern Dietary Treatment. By Margery Abrahams, M.A., M.Sc., Dietitian to St. Bartholomew's Hospital, London, and Elsie M. Widdowson, B.Sc., Ph.D., Biochemist to King's College Hospital, London. Cloth. Price, \$3.25. Pp. 328. Baltimore: William Wood & Company, 1937.

This book gives a concise and informative review of the principles of nutrition. The first part discusses briefly the food essentials and their importance to the human body. The second part deals with the diseases in which dietary treatment is necessary. Examples of diets are given for patients having these diseases, followed by recipes that offer suggestions of how to carry out these diets with a variety of foods and food combinations. The tables of analysis of the English foods, both raw and cooked, add merit to the book. On the whole this volume should be of practical value as a reference book to students of nutrition.

Algunas de las Impresiones y notas de mi última estadía en Norte América. Por el Doctor L. Lopez Villoria. Paper. Pp. 38, with 7 illustrations. Caracas: Academia nacional de medicina, 1937.

This book is a report of the author to the Academia Nacional de Medicina of Caracas on his personal impressions and professional observations during his postgraduate studies in the United States. It shows the large field covered in bronchoscopy and esophagoscopy in the courses given by Chevalier Jackson, Chevalier L. Jackson and some of their most prominent pupils at the University of Pennsylvania. The clinical and surgical work which is performed during the courses, the lectures delivered and the technics shown and other demonstrations are described in detail. The book shows also the development of ophthalmologic and otorhinolaryngologic surgery by American specialists. Special references are given to work and technics of Dr. Ramón Castroviejo of the Columbia Presbyterian Hospital and Simon L. Ruskin of the Harbor Polyclinic of New York. Reference is made also to surgical technics shown and explained in some scientific centers in the United States by well known foreign surgeons. The book is of value especially for specialists in bronchoscopy, esophagoscopy, ophthalmology and otolaryngology.

A Textbook of Medicine. By American Authors. Edited by Russell L. Cecil, A.B., M.D., Sc.D., Professor of Clinical Medicine, Cornell University Medical College, New York City. Associate Editor for Diseases of the Nervous System: Foster Kennedy, M.D., F.R.S.E., Professor of Neurology, Cornell University Medical College. Fourth edition. Cloth. Price, \$9. Pp. 1,614, with 42 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

The first edition of this book was published in 1926 and the third printing in 1933. The fourth edition provides extensive revision, reediting and resetting. Six contributors have died since the publication of the first edition. In the present edition a number of new topics have been introduced. Moreover, the editors and publishers have decided to establish a retiring age for contributions so that new authors and new treatises appear for many subjects discussed by other authors in previous editions. The work is so authoritative, so complete and so thorough that it may be generally recommended as one of the best available works in its field.

Fundamentals of Anatomy. By Carl C. Francis, A.B., M.D., Senior Instructor in Anatomy, Laboratory of Anatomy, Western Reserve University, Cleveland, Ohio. Cloth. Price, \$2.75. Pp. 320, with 176 illustrations. St. Louis: C. V. Mosby Company, 1937.

This is an exceedingly brief survey of human anatomy. The illustrations are excellent. Most of them have been drawn from preparations in the Hamann Museum in Cleveland. Since the brief text includes histology, the anatomy of the nervous system and surface anatomy, as well as the gross anatomy of the rest of the body, it is evident that the account of each structure is exceedingly brief. Five lines are devoted to the hypophysis, seven to the frontal bone, nine to the portal vein, and a trifle over two pages to the entire small intestine.

Clinical Endocrinology. By Samuel A. Loewenberg M.D., F.A.C.P., Clinical Professor of Medicine, Jefferson Medical College, Philadelphia. Foreword by Hobart A. Reimann, M.D., Professor of Medicine and Clinical Medicine, Jefferson Medical College, Philadelphia. Cloth. Price, \$8. Pp. 825, with 194 illustrations. Philadelphia: F. A. Davis Company, 1937.

During the past few years each of the leading publishers in the field of medicine has made available a work on endocrinology. The author of this volume is clinical professor of medicine in Jefferson Medical College in Philadelphia. The book follows established lines and is based on an extensive bibliography from which the author has chosen wisely. In his considerations of the various glands he follows the outline of history, anatomy, physiology, pathology and the diseases affecting the gland in question. The concluding chapters concern undetermined endocrine activities and the significance of laboratory observations. The book is in every sense a practical one and should be useful to the general practitioner as a reference work.

The Mayo Clinic. By Lucy Wilder. Second edition. Cloth. Price, \$1.50. Pp. 96, with illustrations by Ruth Barney. New York: Harcourt, Brace & Company, 1938.

Printed first in 1936, this new edition is handsomely republished and illustrated with charming drawings and pictures; altogether a most satisfactory book.

Miscellany

TRANSFERRING CASE RECORDS TO FILM SOLVES STORAGE PROBLEM

SIXTEEN THOUSAND RECORDS STORED WHERE TWO
HUNDRED WERE STORED BEFORE

STELLA FORD WALKER, CHICAGO
Chief Medical Statistician and Medical Librarian, Cook County Hospital

In the comprehensive program of improvement and modernization now going forward at Cook County Hospital, the transferring of case records to film in the medical record room is attracting considerable interest.

Every hospital sooner or later is faced with the problem of finding space for the steadily expanding file of patients' histories. Cook County Hospital is no exception to the rule, since 50,000, 60,000 and now 70,000 new histories must be accommodated annually. Four basement rooms, in addition to the record room proper, proved to be inadequate and unsatisfactory. Histories damaged by dust and humidity from overhead water pipes or grown fragile with age were destroyed to make room for the constant stream of new histories. The medical staff, recognizing the need for permanent storage of records, talked of constructing a building for the voluminous files. The adoption of a film storage plan dramatically changed the entire picture.

The transfer of written and printed material to film is not in the experimental stage. The Library of Congress has photographed newspapers on 35 mm. film. Many banks now keep a photographed record of canceled checks before returning the checks to their customers. Insurance companies and many industrial companies are using film storage. State and federal departments are finding a solution to the problem of providing permanent storage of important public documents. If Cook County Hospital is the first in the hospital field to adopt this modern method for the storage of medical records, this pioneering is justified because of the bulk of records handled with a limited personnel.

At first questions were raised as to the feasibility of transferring records to film, but the saving in space and filing time

The author wishes to acknowledge the cooperation of Commissioner Frank Bobrytzke, Chairman of the Hospital Committee, and Mr. Anton C. Negri, Efficiency Engineer.

The Cook County Hospital Medical Staff, especially the Committee on Medical Hospital Records, has been most helpful in supporting this and other new procedures for the improvement of Record Room service.

was so desirable that further study of the plan seemed imperative. The many advantages of the method now dominate the picture.

The records are photographed page by page on 16 mm. film and stored on receiving spools similar to those used for 100 feet of motion picture film. The fear of creating a fire hazard was the first objection to be eliminated. The acetate film used will burn as readily as paper but not any more freely, and it is not

Fig. 1.—One drawer of name cards size 5 by 8 inches may be replaced by one small carton of 100 foot 16 mm. film.

explosive. Being stored in small filing cabinets, the film will be less of a fire hazard than the bulky paper records. No special care of the film in storage is required.

The legality of the photographed record is easily established. As long as an original record is available, its production in court can be demanded. When the original is destroyed, the photograph is acceptable as evidence. "The eye of the camera don't lie." (From opinion rendered by Chief Justice Edward Smith, *Tobin v. Knaggs*, June 9, 1937.) As a matter of fact the continuous film, recording one page after another, cannot be changed without detection. Sheets cannot be removed as from a collection of separate pages, and the microphotographs cannot be modified by the use of matching ink and carefully selected pen.

A roll of 16 mm. film (stored in a small carton, as shown in figure 1) is substituted for a drawer containing a double file of name cards size 5 by 8 inches (12 by 20 cm.). An alphabetic file once transferred to film will never again get out of order, no matter how many people have occasion to consult the file.

The work of photographing the records is offset by the elimination of the work of transferring bulky records and by the elimination of trips to distant vaults—the small spools of film being readily stored in the main record room.

Physicians sitting down to read the photographed records for the first time remark on the clearness of the record and the ease with which they can pass over the pages in which they have no interest and find the particular information they are looking for.

The photographing of the records is made entirely mechanical by means of a special camera enclosed in a photographing chamber. As a page is fed into the slot provided, it passes over a roller geared to synchronize with the movement of film past the camera lens. There is no waste of film; long and short pages follow closely on one another. The fixed distance between camera and record sheets and the fixed amount of illumination provided within the photographic chamber make it possible to use film inexpensive as compared with that made for the camera which must accommodate to a wide range of distances and a variety of lighting conditions. The photographing is done as rapidly as the pages can be fed over the roller. The machine can accommodate a speed of 3,000 sheets an hour. An operator has acquired a satisfactory rate of speed who feeds 1,500 sheets an hour accurately without over-riding or picking up more than

one sheet at a time. The film is removed from the camera on 100 foot receiving spools, which are sent to the company's plant for developing.

The projector has a ground glass screen so arranged as to carry a "life-sized" reproduction of the photographed pages (8½ by 11 inches at Cook County Hospital). A small hand crank spins the record to the desired page, guided by serial numbers thrown on the screen to the right of the pages.¹

The ordinary transfer case, holding 200 records of letter-sized paper, will hold 16,000 records on film with each receiving spool protected by a paper carton. However, a special cabinet has been ordered at Cook County Hospital; the drawers will be of the proper depth and will carry three rows of the film rolls. It is comparatively an inexpensive matter to provide locks and fireproof cabinets if they seem advisable.

Hospital inspectors, seeing the method in use, have recognized the advantages of this method over that of storing the original bulky records.

One advantage not at first anticipated, but of major importance, is the inspiration given toward obtaining better records in anticipation of permanent storage. The first intern to see the photographed records at Cook County Hospital said "We should get more on a page and be more careful of what and how we write." Each physician and nurse seeing the projected records expresses similar reactions, and now a number of committees are working in this hospital to select better forms for histories and to supervise the production of records worthy of permanent storage.

The question of how long the original records should be kept before being photographed for film storage is one for the individual hospital to decide; the answer depends on the storage space available, the percentage of records in the files of a given year which may be required for readmitted patients and the protection afforded the original record by folders, closed boxes, dustproof vaults or other means.

By the building of a simple darkroom over the projection table, a means will be afforded for obtaining an imprint from the ground glass of the projector of any page or pages required for any purpose. I am told that if the sensitized paper is purchased in gross lots the cost of obtaining an enlargement will be in the neighborhood of 1 cent a page. Thus if a patient returns to the hospital his record may be reproduced and sent to the ward if the doctor does not find it convenient to get the

Fig. 2.—The rectangle of boxes on the right contains 100 foot rolls of film representing 16,000 case histories; the drawer, which is the same size, contains 200 histories on paper.

useful information directly from the projector. If an old record is required in court, the projector may be conveniently carried into court, so that the film may be projected there, or an enlargement may be prepared. It is predicted, however, that with government departments adopting the method for important documents it will not be long before suitable projectors will be available for court use.

1. The equipment used at Cook County Hospital is supplied by Recordak Corp., a subsidiary of the Eastern Kodak Company. A more detailed description of the equipment and other information may be obtained directly from the companies supplying such equipment.

The cost of film is the main item of expense, the other equipment being merely rented for the required time. It may suffice here to say that the cost will compare favorably with the cost of providing folders and suitable filing cases. At Cook County Hospital a WPA project provides the workers necessary for the photographing. With this advantage on the side of the new method, film storage costs about half as much as folders and file cabinets for the bulk of records eliminated.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Drugs: Pamphlets Not Accompanying Drug as Evidence of Wilful Misbranding.—The defendant, Mrs. Adah Alberty, was convicted under the federal food and drugs act of 1906, as amended, of shipping in interstate commerce certain wilfully misbranded preparations. The preparations were "Alberty's Calcatine," labeled to be used for acidosis, indigestion, "calcium starvation," diarrhea, brain irritation, and a number of other afflictions; "Alberty's Liver Cell Salts" for "ailments marked by excessive secretions of bile and derangement of the liver, gravel, sand in the uterine [sic], biliousness, headache with vomiting of bile, bitter taste, diabetes, trouble arising from living in damp places, malaria, gout"; "Alberty's Lebara Organic Pellets" for acidosis, dormant liver, and other ills; and "Alberty's Anti-Diabetic Vegetable Compound Capsules." The last-named preparation purported, apparently, to be effective only for diabetes. The trial court fined the defendant \$1,000 and assessed against her the costs of prosecution, which amounted to \$1,499.80. The defendant then appealed to the U. S. circuit court of appeals, ninth circuit.

At the trial the government introduced in evidence certain pamphlets written by the defendant and dealing with the necessity for and the use of the preparations charged to be misbranded. These pamphlets were "Calcium, the Staff of Life," "Alberty's Treatment for Diabetes," and "The Hourglass." They had been shipped in interstate commerce and generally distributed but had not been sent with or appended to the preparations. The defendant contended that the trial court erred in admitting this evidence. In the opinion of the appellate court, however, this evidence was not irrelevant. The issue presented was whether the claims on the labels of the preparations were false and fraudulent. These pamphlets were properly admissible to show the defendant's knowledge as to the truth or falsity of the claims on the labels. Obviously, if false and extravagant claims as to "Calcatine," for example, were made in a pamphlet spread abroad by the defendant, it would be persuasive evidence that similar claims on the labels of the preparation were false and fraudulent. The court could find nothing in the record to warrant interference with the judgment of the trial court and consequently affirmed that judgment.—*Alberty v. United States*, 91 F. (2d) 461.

Physical Examinations: Rights of Defendant in Personal Injury Action.—The plaintiff sustained an injury to his back, which he attributed to the negligence of the defendant company. In a suit to recover damages for the personal injury sustained, instituted in the United States district court for the eastern district of New York, the defendant company entered a motion for an order directing the plaintiff to present himself at the office of a physician designated by the company for a physical examination, including the taking of roentgenograms.

Section 306 of the Civil Practice Act of New York provides that in an action to recover damages for personal injuries, the "court, by order, shall direct that the plaintiff submit to a physical examination by one or more physicians or surgeons, to be designated by the court or judge," if the defendant presents satisfactory evidence to the court that he is ignorant of the nature and extent of the injuries complained of. This section,

said the court, is quite definite and does not permit the defendant to designate the examining physician. Such a designation has to be made by the court or judge. The plaintiff argued that, while the court was authorized to appoint a physician and to require the plaintiff to submit to a physical examination, the Civil Practice Act does not authorize the taking of roentgenograms. While it is true, the court said, that at the time the act was passed there were few roentgenograms taken as compared with the present day, nevertheless a physician in the treatment of a bone injury such as was claimed by the plaintiff would be remiss in his duty and guilty of negligence if he did not take roentgenograms. Furthermore, the decisions of the New York state courts are in accord that roentgenograms are proper in a case like the present one.

The defendant further contended that only the defendant's attorneys should receive a copy of the report of the examining physician. But, the court pointed out, a law suit should not be a game of chance; one side should not have an advantage over the other. If the defendant is entitled to a copy of the report, so also is the plaintiff.

The court therefore entered an order appointing a disinterested physician to make the physical examination and ordered the plaintiff to submit to the examination, including a roentgenogram if the examining physician deemed it necessary. To protect fully the rights of the plaintiff and the defendant, the court authorized the plaintiff's and defendant's physicians to be present at the examination conducted by the physician designated by the court. Since the defendant made the application for the appointment of the examining physician, the expenses incident to that examination, the court thought, should be borne by the defendant. In case the examining physician and the defendant were unable to agree on a proper fee, the court indicated that it would fix that fee.—*Mitchell v. Pure Oil Co.*, 20 F. Supp. 1021.

Workmen's Compensation Acts: Jurisdiction of Industrial Commission Over Medical Fees.—The plaintiff, a physician, had on several occasions been employed by the district manager of the defendant company to take care of injured employees. In this case the plaintiff, having been called to treat an employee, was advised by the district manager to "do whatever is necessary to take care of him." The company, however, refused to pay for the treatment and the plaintiff sued at law for his fee. From a judgment for the physician, the company appealed to the Supreme Court of South Dakota.

The company contended that the physician had no right to sue at law, that since it was operating under the workmen's compensation act the industrial commissioner had exclusive jurisdiction in the matter. The Supreme Court, disagreeing with this contention, pointed out that, while as between employer and employee the remedy under the workmen's compensation act is exclusive, physicians are neither employers nor employees within the meaning of the act. The general rule is thus stated in *Ross v. Austin Drilling Co.*, 131 Kan. 824, 293 P. 757:

The Compensation Act, therefore, does not represent a contract either between the physician and the injured workman, or between the physician and the employer of the workman. There is nothing in the Compensation Act which prevents either an employer or employee from making a contract with the physician for services, as such contracts are usually made, and a contract when so made with the physician is free from the terms of the Compensation Act, unless, of course, that act is specifically made a part thereof.

The provision in the workmen's compensation act that "fees of . . . physicians for service under this article shall be subject to the approval of the industrial commissioner" had no reference, in the opinion of the court, to a contract of employment between a physician and an employer.

The company finally contended that the evidence failed to disclose any contract between it and the plaintiff. The court was satisfied, however, that the facts and circumstances disclosed by the evidence were sufficient to justify the jury in finding a mutual intention on the part of the parties to contract. The plaintiff had been employed by the company to treat its employees on prior occasions; under the workmen's compensation act there was a duty on the company to furnish its injured

employees with medical services, and the district manager called the plaintiff and told him to do whatever was necessary to take care of the injured employee. Clearly, in the opinion of the court, this evidence was sufficient to justify the jury in finding an intention on the part of the defendant to pay the plaintiff for his services.

The judgment in favor of the physician was accordingly affirmed.—*Hannon v. Interstate Power Co. (S. D.), 275 N. W. 358.*

Malpractice: Release of Unfounded Claim Against Alleged Tort Feasor as Bar to Action Against Physician.—The plaintiff was accidentally shot in her leg and the defendant physicians, called to attend her, amputated the leg. Subsequently, she executed a written release specifically releasing the person who shot her "from any and all claims, damages or liabilities thereunder whatsoever." In a suit against the defendant physicians wherein she alleged that they negligently and needlessly amputated her leg, the physicians offered the release as a defense. The trial court ruled out a reply interposed by the plaintiff to the effect that in executing the release she had no intention of releasing her cause of action against the physicians and that she signed the release on the representation of the attorneys of both parties that the release in no manner impaired her right to proceed against the physicians. Judgment was given on the pleadings for the physicians and the plaintiff appealed to the Supreme Court of Minnesota.

The law is settled in Minnesota, said the court, that where a person is injured by the wrong or neglect of another and is not negligent in the selection of a physician to treat him, the wrongdoer is liable for all the proximate results of his own act, although the consequences of the injury would have been less serious than they proved to be if the physician had exercised proper professional skill and care. Under this rule of law, the person who shot the plaintiff could have been held liable for the alleged negligence of the defendant physicians. The rule is equally well settled that a release by the injured person of his right to recover damages from the original wrongdoer operates as a bar to an action for malpractice against a physician, and this is so even though the person attempted to be charged as the original wrongdoer and with whom the settlement has been effected was not legally liable. For these reasons, the court concluded that the release was a complete bar to the plaintiff's action against the physicians for malpractice.

The judgment for the defendant physicians was affirmed.—*Ahlsted v. Hart (Minn.), 275 N. W. 404.*

Hospital Associations: Liability to Hospital that Furnishes Services to Members.—An Oregon law authorizes the formation of corporations empowered to enter into contracts "with individuals, families, employees, associations, societies or with employers for the benefit of employees for the furnishing of medicine, medical or surgical treatment, nursing, hospital service, ambulance service, dental service, burial service, or any or all of the above enumerated services or any other necessary services contingent upon sickness, accident, or death." Such a corporation is required to file a surety bond in the sum of \$10,000 as a guarantee "of the due execution of the contracts to be entered into by such corporation . . . in accordance with the provisions of this act." The defendant, the Employees' Hospital Association, duly executed the required bond. It thereafter entered into a contract with the relator, the Hood River Hospital, whereby the hospital agreed to furnish hospital accommodations and services to sundry individuals who were beneficiaries of the Employees' Hospital Association. The association failed to pay the hospital for rendering these services and the present proceedings were instituted by the state, on the relation of the Hood River Hospital, against the association and the surety company to subject the bond filed by the association to the payment of the amount due the hospital. The trial court gave judgment for the plaintiff and the surety company appealed to the Supreme Court of Oregon.

The surety company contended that the protection of the bond extended no further than the beneficiaries of the association and not to a hospital that actually furnishes the services that

the association was organized to render. It is obvious, the court said, that in requiring a bond the statute looks to the protection of persons who become members of the association in order to obtain the benefit of a sort of hospital and medical insurance. Its purpose was to guarantee the fulfillment of the association's engagements in this respect. The association has no hospital of its own nor is it authorized to practice medicine. It therefore delegated to other agencies the actual discharge of the functions with which a state law had invested them. That being so, if these agencies are not compensated under their contract with the association it is reasonable to assume that they will cease to undertake the performance of these services, the association will be wholly without the means to carry out its agreement with its members and their employers, and the latter would lose the benefits which they hoped to gain by joining the association. The language of the statute, the court continued, is broad enough to include contracts which the association makes with others for the furnishing of hospital and medical services to the association's members. Entering into such contracts is assuredly doing a hospital business, and it is such contracts that are required to be guaranteed by the statute. The court was therefore of the opinion that the trial court properly gave judgment for the plaintiff. That judgment was affirmed.—*State ex rel. Hood River Hospital v. Employers' Hospital Assn. (Ore.) 73 P. (2d) 693.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

32: 339-494 (March) 1938

Familial Involvement of Nervous System by Multiple Tumors of Sheaths and Enveloping Membranes: Hereditary, Clinical and Pathologic Study of Central and Peripheral Neurofibromatosis. O. A. Turner and W. J. Gardner, Cleveland.—p. 339.

*Carcinomatosis of Meninges of Spinal Cord and Base of the Brain, Without Involvement of Parenchyma, Secondary to Carcinoma of the Lung. B. J. Alpers and O. N. Smith, Philadelphia.—p. 361.

Neoplasia in Rabbits Following Administration 1:2:5:6-Dibenzanthracene. H. Burrows and E. Boyland, London, England.—p. 367.

Intranucleolar Bodies in Normal and Neoplastic Human Tissue. R. C. Page, J. F. Regan and W. C. MacCarty, Rochester, Minn.—p. 383.

Agglutination Tests in Study of Tumor Immunity, Natural and Acquired. T. Lumsden, London, England.—p. 395.

Influence of Calories Per Se on the Growth of Sarcoma 180. F. Bischoff and M. Louisa Long, Santa Barbara, Calif.—p. 418.

*Immunization Against Neoplasm: Its Effect on Nitrogen Metabolism of the Host. R. H. Oster and W. T. Salter, Boston.—p. 422.

Glycolysis in Tumor Tissue: II. Effect of Certain Sugars on the Hydrogen Ion Concentration and Lactic Acid Content of Walker Sarcoma 319. Frances F. Beck, Ruth Musser, C. J. Carr and J. C. Krantz Jr., Baltimore.—p. 434.

Tumor Growth in Mice One-Fifth Saturated with Deuterium Oxide (Heavy Water). H. G. Barbour and E. Allen, with collaboration of W. U. Gardner, L. C. Strong, J. B. Hamilton, A. Kirschbaum and P. H. Barbour Jr., New Haven, Conn.—p. 440.

Agent and Soil in Experimental Carcinogenesis. W. H. Woglom, New York.—p. 447.

Observations on Intravenous Administration of Colloidal Solutions of Carcinogenic Hydrocarbons in Rabbits. G. V. LeRoy, E. V. Kandel and A. Brunschwig, Chicago.—p. 449.

Metastatic Carcinomatosis of Spinal Meninges.—Alpers and Smith cite a case of primary carcinoma of the lung with metastatic carcinomatosis limited to the meninges of the spinal cord and the base of the brain, particularly the pons. It is suggested that the carcinoma cells extended directly from the lung, along the lymphatic spaces in the intercostal nerves, to the lymphatic spaces of the posterior roots and ganglions of the posterior roots to the spinal meninges.

Immunization Against Neoplasm.—The observations of Oster and Salter confirm the correlation reported by Dodds between immunity to inoculated cancer and a biochemical response to x-rays. Under favorable conditions the two associated phenomena may be induced at will by a standard artificial technic. The finding of the same biochemical response in artificial immunized animals as Dodds found in naturally immune animals suggests that the observation is intimately concerned with the chemical basis of malignant disease. These chemical observations have been observed only in strains of animals which are naturally immune or can be artificially immunized against neoplasm. It is not clear how the absorbed x-radiation produces the reaction. It is conceivable that other agents which mobilize body protein might produce the same effect.

Continuous Drop Feeding for Treatment of Ulcers of Stomach and Duodenum. A. L. Soresi, New York.—p. 39.

Follicular Lesions of Vitamin A and C Deficiencies: Critical Survey. H. Keil, New York.—p. 40.

Value of Cholesterol in Milk.—Stringfield points out that the foods richest in cholesterol are egg yolk, beef and calf brains, kidney and liver, which contain as much as 120 times the cholesterol found in whole milk. At least forty other foods exceed milk in their proportions of cholesterol per hundred grams, including oranges, bread, lean beef, chicken, chocolate, ham and lard. When foods containing cholesterol are eaten, not all of this substance passes directly into the blood stream, much of it being converted by the enzyme cholesterolase into other substances, some of which are excreted and some of which may go to the tissues in the form of esters. The small amount of cholesterol in milk is beneficial rather than detrimental. There seems to be no adequate reason for urging normal persons to curtail the amount of cholesterol in the diet, or to incriminate milk as a factor in the development of any degenerative disease, including all forms of arteriosclerosis.

Malarial Therapy in Neurosyphilis.—Boyd and his associates compare the late results of malarial therapy supplemented by chemotherapy in 190 cases of cerebrospinal syphilis with twenty concurrent cases treated by chemotherapy alone. Of the patients receiving malarial therapy, 55 per cent show improvement or complete remission as contrasted with 30 per cent of those receiving chemotherapy alone. The quartan parasite appears to be the most effective agent for producing the requisite number of severe paroxysms. Best results were secured from the application of malarial therapy to persons less than 30 years of age. Such patients react favorably to fewer paroxysms than appear necessary to produce comparable results in older persons. Better results have been secured from asymptomatic cases than from symptomatic. Of the latter, the cases presenting only organic signs have given better results than those in which mental involvement has existed. The severity of the paroxysms experienced, rather than their

number, appears to have a definite influence on the results secured. It is suggested that the objective of malarial therapy should be the subjection of the patient to a minimum of twenty-one paroxysms which attain a height of 104 F. or more, and that, if the first strain or species of parasite employed fails to produce this minimum, reinoculation with different strains or species should be undertaken until this minimum is reached.

Yellow Fever Vaccination.—Soper and Smith point out that between October 1935 and April 1936 forty-four adults were vaccinated against yellow fever in Brazil with tissue culture virus (17E) and human immune serum. The immune serum used was from pools obtained from two or more persons who had suffered attacks of yellow fever. The dose used was 0.5 cc. per kilogram of body weight. An interval of from thirty minutes to two hours elapsed between injections of the immune serum and the virus. Intracerebral injection into mice of peripheral blood, drawn daily from two men during fourteen days following vaccination, failed to reveal the presence of circulating virus. Thirty-seven of the forty-four persons vaccinated were tested for immunity one month later. Of these, only two were not immunized. One of these was subsequently vaccinated with the same tissue culture virus and immune monkey serum, and immunity developed. The use of cultivated virus and human immune serum appears to be safe and highly effective but impracticable for mass vaccination because of the difficulty in obtaining and administering the necessary amount. During the same period 234 persons were

vaccinated with the same virus and various pools of immune goat serum. Although satisfactory immunization was secured, this method cannot be recommended because of serum reactions and delayed febrile reactions with circulating virus attributed to the rapid excretion of the heterologous serum. In 1936 and 1937 a total of 795 persons were vaccinated with hyperimmune monkey serum and the same tissue culture virus. Antibodies in rhesus serum were more effective than those in goat serum. The relatively high percentage of failure to immunize encountered with this method is attributed to the use of excessive amounts of antibody, resulting in a complete inhibition of activity of the virus. A delayed reaction of unknown etiology occurring from two to eight months after vaccination, the main symptoms of which was jaundice, was reported in from 20 to 30 per cent of a series of vaccinations done with two pools of hyperimmune monkey serum.

Transmission of Jungle Yellow Fever Virus by *Aedes Aegypti*.—According to Whitman and Antunes, two strains of jungle yellow fever virus have been transmitted by the bites of *Aedes aegypti* under laboratory conditions. The M. A. J. strain has been carried through seventeen mosquito-monkey-mosquito passages and the Suarez strain through four. No difficulty has been encountered in maintaining the passages. The minimal incubation period between the infectious meal and the earliest capacity to transmit by bite in *Aedes aegypti* has been from fourteen to fifteen days when the M. A. J. strain is used. The prolonged incubation period may play a part in limiting the importation of jungle virus into towns. Of twenty-seven monkeys infected with the M. A. J. strain, thirteen of seventeen survivors either had no fever or first showed fever after the virus had practically disappeared from the blood stream. In the four remaining survivors and in the ten animals that died, the onset of fever corresponded with the period of maximal circulating virus. The delayed febrile response in nonfatal cases may not be a characteristic of jungle virus but may be related to the pathogenicity for rhesus monkeys of the particular strain of virus used, whether of urban or of jungle origin. If the human response is comparable to that of rhesus monkeys, many cases brought to town for treatment after the onset of fever would no longer be infectious for the local *Aedes aegypti*.

Treatment of Hemorrhage and Shock with Lyophile Serum.—Bond and Wright used lyophile serum intravenously to treat animals that were moribund after experimental shock and hemorrhage. Thirty-one dogs were used and, for the most part, were under light ether anesthesia administered by tracheal

cannula. A few were under sodium amytal, given intraperitoneally. During periods of trauma the ether anesthesia was deepened. The experimental data suggest that solutions of lyophile serum would be useful in the treatment of clinical traumatic shock, surgical shock, severe burns and hemorrhage. However, pending further clinical experience lyophile serum should be given slowly and with caution, and pools of serum should be prepared from donors of single blood type compatible with that of the recipient.

Bacterial Flora of Clean Surgical Wounds.—In studying the bacteriology of surgical wounds and its importance in relation to the problem of wound infection, Ives and Hirschfeld made cultures of the wounds during the actual operation in thirty cases in which there was no infection. With the exception of one thoracoplasty, all the wounds were in the abdominal wall. No case was studied if there was any possibility of contamination with feces, pus, urine or bile. Positive cultures were obtained from the skin in 86 per cent at the start of the operation and in 100 per cent of the cases at the close of the operation. Their observations and those that they were able to collect from the literature justify the conclusion that well over 50 per cent of postoperative infections of wounds are caused by either *Staphylococcus aureus* or *Staphylococcus albus*. These organisms are present in the air of the operating room and on the skin of the patient. They unquestionably contaminate wounds during operations, and they may be recovered from the wounds by suitable culture methods. The incidence of infected wounds can be lowered by eliminating these bacteria from the air and skin. The methods which have been used to sterilize air in the operating room are as yet clumsy and difficult to employ but, until a satisfactory method of preventing the contamination of wounds with staphylococci from the air of the operating room is developed, wound infections will continue to occur.

Relapse in Lupus Erythematosus.—Of thirty-one patients with lupus erythematosus whom Callaway and Stokes "cured" with sodium gold thiosulfate, 75 per cent had relapses. Twenty-three patients gave a history of previous oversusceptibility to sunburn. This proved to be significant, for seventeen of the patients experiencing relapse gave a definite history of relapse following exposure to sunlight. Nervous stress and strain undoubtedly had a part in causing certain of the relapses (seven patients), particularly among high-strung patients in private practice. In these patients relapse seemed to be associated with the appearance of the rosacea complex under stress. Each patient had from one to four relapses. Patients whose involvement was extensive, with many lesions, experienced relapse more often (82 per cent) than patients with mild involvement or few lesions (57 per cent). Relapses occurred without relation to any interval of time. No relation was observed to the total or the average dose of sodium gold thiosulfate.

Cutaneous Hazards in Citrus Industry.—Schwartz lists the cutaneous hazards in the citrus fruit industry as: (1) in growing, dermatitis from fertilizers and insecticides and wounds from citrus thorns; (2) in packing, dermatitis from washing solutions and from hypersensitivity to citrus oils, and (3), in canning, dermatitis and paronychia among peelers, reamers and sectioners, because of hypersensitivity to citrus oils and juices.

No cases of dermatitis were encountered that could be attributed to the dyes used to color the oranges. Spreaders of fertilizer and handlers of insecticides should wear rubber gloves, aprons and goggles. Pickers should wear leather gloves and wrist bands. Packers, peelers, reamers and sectioners should wear rubber gloves. Packing and canning operations should be mechanized to as great an extent as possible.

Intracapsular Cataract Extraction.—Appleman reports his experience with intracapsular cataract extraction in 268 cases from the wards of the Wills Hospital, in 250 of which there were no complications, and in seventy-two cases from private practice. The Knapp method was used in all cases. The intracapsular method was performed in 146 cases in which there were no complications. Vision of 6/12 or better was obtained in ninety-eight cases, 6/6 in thirty-seven cases, 6/9 in thirty-eight cases and 6/12 in twenty-three cases. The classic method of operation was used in 104 cases. Vision of 6/12 or better was obtained in eighty cases. The intracapsular method was used in the seventy-two cases from private practice. Vision of 6/12 or better was obtained in sixty-three. An expulsive hemorrhage occurred in one case, with loss of the eye. Of the eighteen cases in which there were complications the intracapsular operation was performed in thirteen and was considered a failure in twelve because of various subsequent complications. The extracapsular extraction was performed in five cases and was also considered a failure because of complications. The author considers the intracapsular operation the method of choice in cases in which there are no complications because of the smoothness and rapidity of convalescence, the absence of reaction and the visual results obtained.

Mandelic Acid in Pyuria.—During the last seventeen months Summerfeldt and Brown treated fifty-two cases of infection of the urinary tract with sodium or ammonium salt of mandelic acid. Of these, thirty-one cases were acute pyuria and twenty-one were persistent pyuria. The organisms present in the urine were *Bacillus coli*, except in six cases in which they were *Bacillus paracoli*, two cases in which they were *Staphylococcus aureus* and in two cases dysentery, one of which was a *Bacillus flexneri*. Not one of these organisms was resistant to treatment. Of the forty patients treated with sodium mandelate and ammonium chloride the urine of 50 per cent was free of pus and bacteria in from one to seven days after the reaction of the urine was more acid than a pH of 5.8. In 38 per cent sterile urine was obtained in from eight to thirty-four days, while in 12 per cent there was no response to treatment. Of the twelve patients treated with ammonium mandelate, 58 per cent responded to the drug within seven days, while 42 per cent required from nine to twenty-eight days. The patients with acute pyuria responded to treatment more quickly than did the persistent group. Twenty cases were observed for from one to sixteen months. There was a recurrence of the pyuria in four cases, and of bacilluria in three cases. In thirteen cases there was no recurrence of either the bacilluria or the pyuria.

Menace of Sodium Bicarbonate.—According to Latchford, instances of tetany have been reported following the use of sodium bicarbonate. It is difficult to understand the danger of such a simple, common substance. Yet the danger is, as with carbon monoxide, interference with the discharge of oxygen by the circulating hemoglobin. Barcroft showed that sodium bicarbonate was highly pleionectic in its action on hemoglobin. Pleionexy is that condition of the circulating hemoglobin in which it holds on more firmly to its gathered oxygen than in the normal condition (mesonexy) and so gives off less oxygen to the tissues than normally. When pleionexy is present, whether induced by sodium bicarbonate, dibasic sodium phosphate or diminished carbon dioxide content, the tissues fail to receive enough oxygen for their needs and tend to fail in proportion to their oxygen requirements and the degree of the lag of oxygen supply behind oxygen demand. With the onset of pleionexy occurs the development of the anoxic condition, which the organism may or may not survive. Not all degrees of anoxemia are dangerous, but all tend to produce tissue breakdown. Failure is inevitable if the tissues of the individual cannot endure the anoxic breakdown. Sodium bicarbonate shifts the disso-

ciation curve of hemoglobin to the left, decreasing oxygen supply to the tissues, producing pleionexy, which as a result of treatment does not appear justifiable, owing to the fact that immediate interference with oxygen supply follows its absorption.

Effect of Prolactin on Secretion of Milk.—Ross gave prolactin to nursing mothers so that he could observe its efficacy on the secretion of milk. The breast milk was pumped by an Abt electric breast pump and the amount obtained was measured carefully. Infants were selected who did not show signs of weight increase by the fifth day. Breast milk was then pumped from the mother and the total twenty-four hour secretion was measured for one or usually two days. Nine mothers received two intramuscular injections of 2 cc. of prolactin (80 Riddle units) and on the second day two intramuscular injections of 3 cc. and twelve patients were given a similar volume of prolactin containing 100 Riddle units per cubic centimeter. A group of ten patients acted as controls and received a similar amount of saline solution. The breast milk was pumped at intervals of four hours until the patient was discharged. No untoward reactions were noted with the less concentrated prolactin. With the more concentrated prolactin, however, reactions consisting of redness and induration varying in diameter from 2 to 15 cm. developed in 83 per cent of the cases. These cleared up in from two to three days. There was also a rise in temperature of from 100 to 102 F. in all but one case after the injections but it returned to normal in from two to six days. The higher concentration of prolactin administered increased slightly the secretion of breast milk during the remainder of the patient's stay in the hospital. Of much more significance, however, was the fact that seven of eleven patients receiving this higher concentration of prolactin, observed after discharge from the hospital, nursed their infants completely, whereas of eight such observed patients receiving the lower concentration of prolactin only two were able to nurse their infants completely. Of the eight controls, only one nursed her infant completely.

Pulmonary Changes in Rheumatic Fever.—Melnick reported necropsies on six patients with acute rheumatic fever. They had complained of joint pains, fever and dyspnea and palpitation. The physical signs were sufficiently clear so that a correct clinical diagnosis of acute rheumatic fever could be made. The postmortem observations, in all the cases, were those of acute rheumatic fever, with verrucous eruptions on one or more valves and Aschoff nodules in the myocardium. In four cases there was no fibroplastic deformity of the heart valves. The consistency of the lungs in all the cases was boggy or rubbery, yet the surfaces that were cut were dry; that is, there was no fluid in the air sacs. In addition, in three cases the surfaces that were cut revealed wide bands which were redder and firmer, having the consistency of spleen tissue; i. e., focal areas of "splenization." The essential microscopic changes were those of an intense hyperemia and a proliferation of the septal cells. The alveolar walls were greatly thickened up to ten or more times the normal. The capillaries in the alveolar walls showed an extreme dilatation, often bulging into the alveolar spaces. There was an increased cellularity of the alveolar wall. The process was seen especially intensified in the focal areas of splenization in three cases. The smallest branches of the pulmonary artery showed changes which may be significant. The endothelium of these vessels was much swollen, cuboidal and even columnar, and vacuolated. No bacteria could be found in any of these lungs except in one case complicated by a confluent bronchopneumonia. The process resembles an allergic reaction. The concept that rheumatism has certain allergic aspects has recently come into greater prominence. In rheumatism the Aschoff nodule in the myocardium is probably an allergic granuloma, according to Klinge and others. Similar rheumatic nodules have been found in almost every organ in the body. The process seen in the lungs in acute cases of rheumatic fever is probably one of the hyperergic mechanisms that occur in this disease.

Endometriosis.—In a review of 507 consecutive pelvic laparotomies done by Hurley and his senior associate during three years, endometriosis was found in forty-nine cases. In all except three the entire disability was produced by the endometriosis. All were proved to be endometriosis by microscopic examination. Ectopic endometrium can be found in many locations. It is best classified as internal or external endometriosis. The progress or retrogression of endometriosis depends on the presence or absence of hormone stimulation from the ovary. Two methods of treatment are available. Surgical removal of the growth when possible is to be desired in all large lesions and in all patients less than 40 years of age. In patients who

have extensive involvement of both ovaries, a small amount of ovarian tissue can usually be spared regardless of how extensive the growth has become. In cases in which small amounts of ovarian tissue have been saved there have been no recurrences up to the present time. If the peritoneum and intestine and pelvic organs are extensively involved, resection of most or all ovarian tissue will effect a retrogression of the lesions to such an extent that almost complete symptomatic relief will occur. Only adhesions will remain if this procedure is carried out. Roentgen therapy is indicated only in patients more than 40 years of age, with lesions that are not large and in whom one feels certain that the diagnosis of endometriosis is correct. Internal adenomyosis or endometriosis of the wall of the uterus is not helped by curettage.

Differentiation of Encephalitis Viruses.—Webster states that poliomyelitis, Japanese B encephalitis, Australian X disease and St. Louis encephalitis have features in common but are distinguishable by laboratory tests. Outbreaks of each are frequent and limited chiefly to hot weather. Each may be recog-

nized by testing serums of convalescents for specific neutralizing properties against one of these virus agents or by obtaining virus from the cerebral tissue of fatal cases and testing its virulence for mice, monkeys and sheep and its neutralization in specific antisera. The sheep virus is probably infectious for man. Louping ill virus has been related to the virus associated with X disease of children in Australia and now has proved similar to the newly discovered Japanese B encephalitis virus. Laboratory tests on susceptible animals indicate clearly that the most vulnerable port for the experimental introduction of these viruses is the nasal mucosa: this is the route of choice in mice for the St. Louis virus, in mice, monkeys and sheep for the Japanese and louping ill viruses and in monkeys for the poliomyelitis virus. There is also evidence that spontaneous louping ill may occur both in man and in mice through the nasal mucosa. But contact experiments to induce spontaneous transfer of St. Louis, Japanese B and poliomyelitis infections among susceptible laboratory animals have failed and it is difficult or impossible to detect the virus in the upper part of the respiratory tract of the diseased individual. Subcutaneous injections of Japanese B and louping ill viruses in mice and of poliomyelitis virus in monkeys and possibly in man may also induce disease. Reports state that in nature louping ill infection of sheep takes place subcutaneously by the bite of an insect. Experiments to detect virus in the blood of individuals following natural or experimental infection are either positive for brief periods only (louping ill and Japanese B viruses) or are completely negative (poliomyelitis and St. Louis viruses). Hence there is evidence for and against both the upper respiratory and subcutaneous routes of transmission of these infections and the question remains perplexing.

Cutaneous Eruptions from Exposure to Hydrocarbons.—Because of the potential hazard of acneform eruptions in workers exposed to chlorinated hydrocarbons used in manufacturing, Mayers and Silverberg made a survey of twenty-two industrial plants using such materials. Three of these plants made insulated wire and the remainder made electrical condensers. The eruption, which is characterized by pustules, papules and comedones, may or may not become disabling. It usually occurs within the first few months of employment. The incidence of the acneform eruption appears to be higher in the summer than in the winter. The acneform eruption differs from the acne commonly found among adolescents in the following important respects: 1. There is severe pruritus, which seldom accompanies acne vulgaris. 2. Acne is associated with a dermatitis venenata or a paronychia of the fingers, especially the index fingers. 3. Comedones are far more numerous, more closely crowded together to form patches. 4. The distribution is along the exterior surfaces of the arms and especially around the elbows. 5. The condition may be transferred to other members of the family by contact with the skin and clothing, when these have a coating of the chlornaphthalene on them. The eruption may in severe cases involve the deeper layers of the skin and result in permanent scarring. In severe cases there is a tendency to secondary infection, especially when there is a coexisting pruritus and the worker scratches the lesions. Attention to adequate local and general ventilation, personal hygiene on the part of the workers and adequate intelligent medical supervision will effectively eliminate the hazard. Fumes and vapors should be exhausted laterally at their source, the velocity of air being maintained at 1,000 feet per minute. Employers should supply workers with highly starched uniforms, underwear, caps and gloves. These should be laundered every day. Two lockers should be provided, one for street clothes and the other for uniforms. Washing up before lunch and before leaving work at night should be done under supervision. Since the chlorinated naphthalenes are not soluble in water, the waxlike film which is deposited on the skin should first be removed with cold cream,

in which it dissolves. Workers should then wash thoroughly with warm water and a mild soap. A shower before leaving work is desirable. All workers should apply a protective lotion to all exposed parts of the body before starting work. They should be encouraged to report promptly any evidence of a cutaneous eruption or of general ill health.

Pneumoperitoneum in Pulmonary Tuberculosis.—Bennett states that during the last two years pneumoperitoneum has been induced in 200 patients. Thirty-two of these patients have died since, after an average of about eight months of treatment. Necropsies were performed on fifteen. In view of the advanced stage of the disease in most of these patients this case fatality rate cannot condemn pneumoperitoneum, especially since the necropsies did not indicate that this was a factor responsible for death in any case but one, in which instance it accelerated what was otherwise an apparently certain death. Clinically and symptomatically, improvement was noted in more than half of the patients treated. A careful analysis was made of the cavities in 120 of these cases; 90 per cent showed cavitation with a total of 211 cavities. Of the 211 cavities, 22 per cent of those in the upper third, 33 per cent of those in the middle third and 31 per cent of those in the lower third could not be visualized roentgenologically after pneumoperitoneum had been well established. Reduction in the size of cavities was noted in an additional 12 per cent of those in the middle third. The remainder of the cavities showed no change or became larger, or more recent roentgenograms were not available because of the short duration of the treatment or the departure of the patients. In eleven patients showing infiltrative lesions without cavitation, four showed marked clearing of infiltration under pneumoperitoneum. Fifteen of the 200 patients after a period of artificial pneumoperitoneum underwent thoracoplasty or extrapleural pneumothorax who previous to the addition of pneumoperitoneum were in too poor condition or had too much contralateral disease to withstand these more radical operations. Pneumoperitoneum did not prove particularly effective when used in an emergency to control hemorrhage. A change from a previously positive to a negative sputum, following the establishment of pneumoperitoneum, occurred in fifty-seven patients out of the 173 whose sputum had been positive prior to the institution of this form of treatment.

Immobilization and Posture in Infections of Extremities.—During the last two years, Wangenstein has treated a variety of acute infections by immobilization in windowed (for drainage) plaster casts. Immobilization in plaster reduces movement to a minimum. Immobilization by splints or traction does not approximate the security and rigidity lent by adequate immobilization in plaster. The lymphatics ramify in the fascias overlying the muscles. The importance of keeping muscles as quiet as is physically possible in phlegmonous inflammations is therefore understandable. Elevation of the infected part is a valuable addition to this mode of treatment—particularly when the inflammation concerns the soft tissues. Increased relief of pain and quicker reduction of swelling are obtained.

Gonococcal Arthritis.—Spink and Keefer treated twenty-six of their patients (group 1) medically. In group 2, twenty-four patients had sufficient evidence of an effusion into one or more joint spaces to warrant aspiration of the synovial fluid in addition to medical therapy and group 3 was composed of twenty patients whose joints were aspirated and also opened and followed by lavage. Two of the group 1 patients died. On leaving the hospital (average stay fifty days), eighteen patients were completely free of all joint symptoms, with no limitation of motion and no x-ray evidence of destruction of the joints; of the remaining six, one ultimately had a complete bony ankylosis of a wrist joint, one had x-ray evidence of destruction of one metatarsal joint but no limitation of function, two had a partial ankylosis of the wrist joints and two had a residual soreness of the joints of the lower extremities, which disappeared after several weeks. The average stay in the hospital in group 2 was fifty-three days. The aspirated synovial fluid from twenty-two of the patients was sterile. Infected fluid was aspirated from the shoulder joint of one patient and from the wrist joint of another. None of the group died. Follow-up observations on these patients revealed that only one had a recurrence of joint symptoms. This followed a second attack of gonococcal urethritis. Fourteen patients had complete recovery of the function of their joints with no x-ray evidence of their destruction. Two patients had bony ankylosis of a wrist joint. One had a hyperflexion deformity of the toes. Another had destruction of the metatarsal joint of the first toe but no limitation of function. The remaining six patients had residual periarticular adhesions of the knee joints with slight limitation of motion on flexion (from 10 to 20 degrees) but no limitation on extension. Gonococci were recovered from the synovial fluid of fifteen patients of group 3, while the fluid from five was sterile. The average stay in the hospital was sixty-one days. Only three patients ultimately had no limitation of motion of joints. Six had an ankylosis of one joint with less than 10 degrees of joint motion.

Three patients were capable of only 50 degrees of motion of one knee joint. Eight patients had periarticular fibrosis of one knee joint with from 10 to 15 degrees of limitation of motion on flexion but with full extension.

Urea in Treatment of Wound Infections.—For the last year Baker has used from 25 to 30 per cent solutions of urea for the treatment of wound infections. Results have been uniformly gratifying. It has been found to be stable in solution, nontoxic and remarkably effective in the removal of wound exudates, bringing about normal repair of tissues through its passive mechanical cleansing action. The material has been used in the same concentrations for the irrigation of wound sinuses. Open wounds demonstrating infection, fistulas or sloughs of the abdominal wall following operation, chronic discharging ulcerous areas, sinus tracts resultant from chronic bone infections and the like have undergone treatment with urea. Within a few days after institution of treatment the indolent areas of the wound begin to assume a freshened pink appearance and have a tendency to bleed freely. Wound exudates are readily extruded. Improvement is definite and continued. The odor from draining wounds is reduced to a minimum, often disappearing entirely. Pain due to prolonged use may be overcome by either reducing the strength of the solution slightly or by the use of a mild sedative before renewing the dressings or beginning the irrigations.

Fever Therapy in Cutaneous Disorders.—Litterer and Phillips used fever therapy in the treatment of 167 cases of cutaneous diseases (eczematoid, erythema multiforme, psoriasis, endocrinopathies, urticaria and seborrheic dermatitis). In the eczematoid group a 96 per cent immediate response was obtained and this high improvement continued well into the fourth month of observation. Between this and the fourth year a relapse of 31.25 per cent was observed in those patients who received a complete clinical remission of their cutaneous lesions immediately after the course of fever treatments. The immediate response in the erythema multiforme cases revealed a complete resolution in 90 per cent, which again extended well into the fifth month. But over a period of two years there was a relapse ratio of 33⅓ per cent. Psoriasis revealed a 50 per cent immediate response, but within four years 33⅓ per cent had relapsed. The immediate response of endocrine cases to fever therapy with complete abeyance of their cutaneous manifestations was 80 per cent. After four years there have been no relapses. Only a 62.5 per cent immediate response was obtained in urticaria and 60 per cent of these relapsed. In addition to these eighty cases, a group of seventy-five cases has been studied over the last seven years with reference to the part played in the etiology by underlying systemic conditions. In more than 90 per cent there can be demonstrated by thorough study abnormal upsets in one or more of the gastrointestinal, liver and biliary or endocrine systems. When these conditions are isolated and the treatment consists of correcting them in addition to fever therapy, the immediate response immediately rises to 85 per cent and the relapse ratio drops to 25 per cent. So successful has this combined management been that the authors have practically discontinued cutaneous testing and attempted desensitization in urticaria. The results are decidedly encouraging and justify further investigation. Much light is thrown on the mechanism of both the etiology and the response of these cutaneous disorders by a study of physiologic and biochemical changes already established during fever therapy. The two great regulators of body temperature balance in normal man are the heat regulating mechanism in the brain base and the proper function of the skin. Temperature changes at the base of the center of the brain invoke an immediate reflex response in the circulation at the surface with an associated fluctuation in the elimination of water and crystalloids through the excretory ducts. Fever therapy exerts its benefit by striking at the mechanism of the lymph space.

Intubation of Small Intestine.—In a fairly large group of patients with gastrointestinal obstruction, gastroduodenal suction is not enough to relieve the distention. In a still larger group, though the distention is relieved, the location as well as the nature of the obstructive lesion is still unknown. Abbott and Johnston offer a method (intubation) of management that will often decompress the abdomen by completely emptying the entire small intestine proximal to the obstruction and has enabled a restitution of normal intestinal action without the necessity of surgical intervention. Moreover, having advanced the tube to the point of obstruction, one can often, by the study of aspirated intestinal contents and by the injection of a minimal amount of an opaque medium through the tube, identify both the position and the nature of the obstructing lesion. Whenever gangrene of the intestine is suspected, operation must continue to be the treatment of immediate choice. The procedure is based on the method described by Miller and Abbott for intubation of the small intestine. Intubation for the relief of intestinal obstruction has been attempted in sixteen cases with failure in only three. While the symptoms in one or two instances were mild, the patients were desperately ill. In nine instances function returned spontaneously following a variable period of decompression. Paralytic ileus and organic obstructions have responded in an essentially similar fashion. In the four cases in which the obstructing lesion was studied roentgenologically after the injection of a barium sulfate suspension through the tube, the point of closure was identified and the end of the tube was found to be lying within a finger's length of the obstruction itself.

Primary Fibroblastic Brain Tumors.—Gardner and Turner present three cases of primary fibroblastoma of the choroid plexus of the lateral ventricle. All three tumors were removed at operation. The intraventricular location of the tumor was not suspected from the clinical signs and the exact localization was made only at operation. The tumors were of mesodermal origin and probably arose from the fibrous elements of the choroid plexus or tela choroidea. There is no clinical picture that will localize an intraventricular growth, although there are certain neurologic features which may at times direct attention to the possibility of a lesion in this location. This is particularly true when localizing signs are absent in the presence of an obviously expanding intracranial lesion. Periodic headaches or intermittent attacks of increased intracranial pressure have both been cited as the most suggestive evidence of a growth within the lateral ventricle. This periodicity is due to the ball-valve action of the tumor and can occur in other parts of the ventricular system; namely, in the third ventricle. When the large size of the tumor prevents it from moving freely or when local adhesions fix the tumor in one position, this phenomenon may be absent. Obvious signs of increased intracranial pressure may be late in developing in young patients, since in them cranial suture separation may serve to decompress the brain until the bulk of the tumor plus the concomitant cerebral

edema overcomes this compensation. Hemianesthesia and hemiplegia have been pointed out as the most important localizing evidence. Intraventricular tumors appear to occur most frequently during the first three decades of life. While in many instances the symptoms are less than one year in duration, there are wide variations. In tumors in this location, the duration of symptoms is no index of the malignant condition of the growth since, by reason of their location, they may block circulation of the cerebrospinal fluid and produce fulminating signs of increased intracranial pressure, despite the fact that they may be encapsulated and perfectly benign.

Congenital Steatorrhea Due to Pancreatic Defect.—Harper reports eight cases of congenital steatorrhea with the results of postmortem examination in four. The symptoms common to all these babies were failure to thrive on a normal diet, even on breast milk, and the peculiarity of their stools. These were bulky, frequent and offensive, with a rancid odor and of a pale creamy color or pale green. Oily material was passed with the stool and separately. As the children became older, x-ray examination of the bones showed osteoporosis, the teeth were badly developed, anemia became evident, sometimes of the macrocytic type, and there was great susceptibility to respiratory infections. Microscopic examination of the pancreas in those cases in which a necropsy was obtained suggests a failure of development of the gland. The conclusion arrived at after reviewing the material available in the literature and the cases reported here is that, in cases in which there is evidence of the passage of fatty stools from birth (particularly butter-stools) with failure of nutrition, the diagnosis of a congenital defect of the pancreas can reasonably be made.

Undulant Fever in Children.—Paterson and Hardwick encountered eight cases of undulant fever in children between the ages of 6 and 14½ years. Children comprise the largest milk-consuming section of the community, but the rarity of the disease among them has not yet been satisfactorily explained. It is probable that many cases are never recognized. Of the eight patients the youngest was 6 years old and only one was a girl. The beginning of the illness was abrupt, with signs of an infection of the nasopharynx, and the diagnosis was either that of a common cold or of influenza; it was only the persistence of the fever that attracted attention. In four instances the bouts recurred over a period of four months; in one case they persisted for a year. Agglutinations were positive in every case to a titer of 1:500 or higher. With 0.2 cc. of a vaccine containing both abortus and melitensis organisms, cutaneous tests were done on the patients and a strongly positive reaction was obtained in each case. The cutaneous test by itself, that is, without a positive agglutination, does not give reliable evidence of the disease.

Spontaneous Hematomyelia.—Richardson cites four cases of spontaneous hematomyelia. In the first case there was a small angioma in the first lumbar segment of the spinal cord which had ruptured, causing a central hemorrhage from the fourth thoracic to the lowest sacral segment. The angioma was considered a developmental vascular lesion rather than a tumor. The second case was one of old hematomyelia occurring with syphilitic meningomyelitis. A central hemorrhage occurred from the ninth thoracic to the fifth lumbar segment,

leaving an elongated strip of gliosis containing a large amount of old blood pigment. The third case was one of cervical hematomyelia in which the exact cause was not demonstrable, since pathologic examination was incomplete. In the last case hematomyelia was not fatal but left permanent sensory and motor changes resembling those of syringomyelia. Traumatic hematomyelia has assumed a false position of importance in the incidence of true hematomyelia. Hemorrhage is often overstressed in the conception of the pathologic changes due to injury of the spinal cord. Spontaneous hematomyelia should be considered as primary, nontraumatic hematomyelia and is probably always due to disease or maldevelopment of the spinal vessels. Vascular maldevelopments, similar to the maldevelopment found in the first case, comprise one of the commonest known causes of the condition.

Vascular Lesions in the Brain with Brain Tumors.—Moore and Stern examined 130 brains in which brain tumor or abscess was present for evidences of vascular lesions. The first hundred were from a consecutive series of necropsies, and fourteen showed accompanying vascular lesions either in the pons, midbrain or occipital lobe. In addition to these fourteen cases, four showing vascular lesions were examined among the remaining thirty brains of the entire group. Five of the total of eighteen cases of hemorrhagic cases presented the gross appearance of occipital lobe infarction and lesions of the brain stem in the others. Fourteen cases were studied histologically in frozen and celloidin sections. The basilar artery and its branches and the posterior cerebral and its calcarine branches were dissected out, embedded in paraffin, stained and studied. With the exception of one case (softening in the peduncular region), the lesions of the brain stem consisted of multiple fresh hemorrhages from the arteries. Histologically they resembled hemorrhages in arterial hypertension. The occipital lesions are hemorrhagic or ischemic infarctions. It is suggested that sudden changes in the pressure relationship between the supratentorial and infratentorial spaces lead to disturbance of the circulation in the area of the rostral end of the basilar artery. Compression of the posterior cerebral artery causes occipital infarction. Arterial congestion in the basilar artery causes a predisposition to hemorrhages which are finally brought on by a reflex rise of the systemic blood pressure. Surgical procedures seem to have no pathogenic significance. The clinical picture of the hemorrhages of the brain stem is that of a sudden onset of unconsciousness. They seem to be fatal in every case. The occipital lesions have their clinical counterpart in apoplectiform manifestations or visual disturbances which complicate the neurologic picture.

Vitamin C Deficiency in Peptic Ulcer.—Portnoy and Wilkinson examined the blood content and the urinary excretion of vitamin C (cevitamic acid) by six methods in fifty-one control subjects, twenty-five patients with peptic ulceration and thirty-one patients with hematemesis. With the urinary excretion method, groups of normal controls, miscellaneous ward controls, patients with peptic ulcers and patients with hematemesis excreted mean daily amounts of 29, 17, 7 and 7 mg. respectively. With the saturation test it was found that to

produce a 50 per cent excretion of the administered cevitamic acid the normal controls, patients with peptic ulceration and patients with hematemesis required from 500 to 2,300, 2,100 to 5,000 and 2,000 to 8,000 mg. respectively. The initial plasma cevitamic acid value (normal from 0.6 to 1.85 mg. per hundred cubic centimeters, patients with peptic ulceration and hematemesis from 0.14 to 0.59 mg. per hundred cubic centimeters) was an approximate measure of the vitamin C nutrition of the body tissues. In an oral cevitamic acid tolerance test (after 1,000 mg. of cevitamic acid orally) the maximal plasma cevitamic acid value was reached in from one to two hours, while the maximal urinary excretion occurred in from four to six hours; in normal controls there was a good response in both blood and urinary levels, while in the ulcer and hematemesis cases the response was negligible. The maximal plasma cevitamic acid value, determined by an intravenous tolerance test, was reached in from fifteen to twenty minutes after the intravenous test dose of 1,000 mg. of the acid, while the maximal urinary excretion occurred some two hours later. The results of the intradermal test for vitamin C deficiency agreed very closely with those of the other tests, decolorization times longer than ten minutes indicating vitamin C deficiency. The severest degrees of vitamin C deficiency were found in the patients with hematemesis. It is suggested that large doses of vitamin C should be given to patients with peptic ulceration and hematemesis.

Vitamin C Deficiency in Peptic Ulcer.—Bourne used Gothlin's capillary fragility method in examining patients with gastric and duodenal ulcer, cases of various diseases and normal subjects of both sexes. The lowering of the capillary resistance in cases of gastric ulcer is traceable directly to deficiency of antiscorbutic vitamins in the diet. The results were not of such a clearcut nature in the duodenal ulcer cases but there is little doubt that patients who have been on the dietary regimen usually prescribed for more than ten days show a definite increase in capillary fragility unless the diet has been supplemented with some potent source of antiscorbutic vitamins. The genesis of peptic ulcer could not be correlated definitely with deficiency of antiscorbutic vitamins in the diet, but the possibility that it may have a part cannot be excluded. It seems more likely that the deficiency of antiscorbutic vitamins in the therapeutic diet may be a factor influencing the transition from the acute to the chronic condition.

Glasgow Medical Journal

11: 113-160 (March) 1938

- *Weil's Disease: New Occupational Disease in Fish Workers. L. S. P. Davidson.—p. 113.

Weil's Disease.—A study of 130 fish workers in Aberdeen in whom Davidson obtained positive serologic evidence of previous leptospiral infection suggests that Weil's disease occurs in three grades: (1) latent or subclinical infection, with or without insignificant symptoms, (2) mild infections with pyrexia and malaise but without jaundice and (3) severe infections with marked prostration and jaundice. The first group can be recognized only by serologic tests. The second group may be suspected if the illness occurs in an individual working in an occupation peculiarly liable to Weil's disease, but serologic tests are essential to confirm the suspicion. Cases in group 2 are usually diagnosed as influenza or tonsillitis. The third group has a symptomatology and course so typical that the clinical diagnosis can often be made with assurance. Since there can be no Weil's disease without rats, a campaign for the extermination or reduction of the rodent population is of paramount importance. Since it is fish remnants which attract the rats and since the spirochetes live in the slimy water, care should be spent in the removal of all offal at the end of each day's work. Half an hour before work commences in the morning the floors, benches and tables should be vigorously hosed with water and thereafter treated with a suitable disinfectant; a hypochlorite solution has a lethal effect on leptospirae in a dilution of 1:4,000. A high degree of immunity can be obtained from the subcutaneous inoculation of killed vaccines of *Leptospira icterohaemorrhagica*. Treatment on the general lines suitable for any severe febrile disease is required. A reduction both in the mortality of the disease and in the

severity of the toxemia has been shown to result from anti-leptospira serum, particularly if the serum is given early; i. e., within the first four days. After the seventh day, when the septicemic stage is over, the beneficial effects are much less marked. The amount of serum advocated is from 10 to 20 cc. given intramuscularly or intravenously, the dose to be repeated in from four to six hours as required.

- Aronson's Streptococcus: Experimental Study. J. W. Howie.—p. 367.

Estimation of Fragility of Erythrocytes.—Creed describes a method of estimating the fragility of red blood corpuscles which he believes gives more consistent and accurate results than methods previously employed. It consists in the addition of measured quantities of aerated whole blood to sodium chloride solutions of varying concentration, prepared by a dropping technic from a stock 25 per cent solution. The percentages of corpuscles hemolyzed and left unhemolyzed are estimated by matching against a series of color standards. The effect of the venosity of the blood on fragility is considerable, but preliminary aeration of the blood reduces the fragility of samples of varying venosity to a constant level. Variations in the p_{H} of the distilled water employed are a possible source of error in fragility determinations, but their effect is minimized by using whole blood in a dilution of 1:25. Anemia of itself increases resistance to hypotonic saline solution and must be taken into account in interpreting fragility curves. In normal persons the concentration of sodium chloride which hemolyzes 4 per cent of the corpuscles varies between 0.41 and 0.45 per hundred cubic centimeters and the concentration hemolyzing 50 per cent of corpuscles varies between 0.36 and 0.4 per hundred cubic centimeters. The fragility curve of a given normal person remains constant over long periods.

Fragility of Erythrocytes.—The method that Dacie and Vaughan used in estimating fragility was a modification of that of Creed. The calculated normal median fragility measured on fifty normal subjects is 0.366 Gm. per hundred cubic centimeters of sodium chloride, the healthy range being from 0.334 to 0.398 Gm. Red cell fragility is closely related to cell dimensions expressed as the mean corpuscular thickness divided by mean corpuscular diameter ratio. The latter may be termed an intrinsic factor influencing fragility. Increase in this ratio is associated with increase in fragility, but the reverse is not necessarily true. Extrinsic factors influencing fragility are the oxygen and carbon dioxide tension of the blood and the temperature and p_{H} of the hemolytic solution. Anemia produces an apparent reduction in fragility. This is partly due to the increased amount of plasma contained in any drop of blood, partly to change in cell volume resulting from oxygenation. Chemical variation in the cell constitution may also be important.

- Carbohydrate Metabolism of Fetal Dog Under Influence of Insulin. H. Schlossmann.—p. 219.

Salt Deficiency and Extracellular Fluids.—McCance found that experimental deficiency of sodium chloride in man produced: 1. A reduction in the volume of the body fluids in which injected sucrose or inulin was dissolved (the extracellular fluids). Reductions of from 28 to 38 per cent were observed. 2. A fall in the concentration of sodium, a rise in the concentration of potassium and no consistent change in the concentration of chloride in resting saliva. 3. A variable reduction or little change in the free and total hydrochloric acid and in the total chloride of gastric juice. These changes bore no close relationship to the simultaneous chloride changes in the plasma. There was also a small fall in the sodium and a rise in the potassium in the gastric juice. 4. A fall in both sodium and chloride of cerebrospinal fluid. 5. A considerable but variable fall in the concentration of sodium chloride in sweat. "Adaptation" to repeated sweating did not contribute to this result.

Vitamin B₁ in Urine as Index of Nutritional Level.—Harris and his associates report data for various classes of subjects. Normal well nourished controls excreted on the average about 20 international units of vitamin B₁ daily. A group of "surgical" patients, who came from a lower social class in a poor industrial area and most of whom were known to have been on diets low in vitamin B₁, excreted only one third of this "normal" figure. Somewhat lower values were seen in a group of miscellaneous medical cases (average 5 international units daily). The lowest figures of all—excretions of 3.5 international units daily and less—were in cases of beriberi and polynuritis of nutritional origin. Low values were seen also in a proportion of the cases of polynuritis which had been judged on clinical grounds to be not primarily of nutritional origin. Responses to test doses were approximately parallel with the "resting levels" and served to confirm the separation into the foregoing categories. It is concluded that the urinary excretion furnishes a useful guide to the state of nutrition of the subject with regard to vitamin B₁. The low values so often found in medical cases may probably be attributed to one or more of the following causes: anorexia, poor hospital diets, raised metabolism (especially in fever), wasting of body tissues and faulty absorption or utilization. The importance of providing specially nourishing food during illness and convalescence is emphasized by these results. A "resting level" of excretion

of from 10 to 20 international units daily and a response of upward of 30 international units after the standard test dose (350 international units daily) implies average normal nutrition. Probably with the more advanced state of avitaminosis the most accurate indication of the degree of the deficit can be obtained by a determination of the number of repeated test doses which are needed before "saturation" is finally brought about at the normal level.

Treatment of Infected Wounds with Urea.—The procedure that Muldavin and Holtzmann used in the treatment of 170 cases of variously infected wounds with urea crystals is as follows: The wounds were syringed free from pus and necrotic material with a saturated solution of urea, excessive moisture was removed and urea crystals were then liberally applied. Waxed paper was placed next to the crystals to keep them in contact with the wound and to prevent the dressings from becoming soaked. This had the further advantage that it prevented the dressings from sticking to the raw surface of the wound. In all but small wounds zinc cream was spread over the adjacent skin. This was used as a precaution, since some moisture will reach the surrounding skin however carefully discharging wounds are dressed. Owing to the extreme diffusibility of urea when combined with a saturated solution for syringing, even the deepest wound can be treated effectively. After two or three applications, sloughs disappear and also any foul odor. Replacing the slough is a highly vascular granulating surface. However sluggish the local metabolism may be, this response apparently can be relied on and is often spectacular. Septic burns under this treatment become clean and form granulations so quickly that the surrounding epithelium is able to grow in with but little delay. The same prompt response is often obtained in varicose ulcers. The time taken for complete healing of the ulcer depends on its size and depth and on its chronicity. The response of superficial abscesses is good; the area of induration surrounding an abscess was eliminated in some and diminished in all cases by the urea. In the treatment of carbuncles, urea could be relied on to free the area of the wound from necrotic material. There is no evidence that urea directly stimulates epithelization. For this reason urea cannot be used as an "all purpose" casualty dressing. Urea does not exert an osmotic effect, no matter how applied, since cell membranes are freely permeable to it; i. e., any strength of aqueous urea solution will hemolyze blood. Pain experienced as the result of the application of urea cannot be due to an osmotic effect.

Parenteral Administration of Vitamins A and D.—Leak discusses his experience with the administration of a concentrated oily preparation of vitamins A and D by intramuscular injection. Some 1,500 injections have been given. The preparation used contains as its active ingredients 60,000 international units of vitamin A and 10,000 international units of vitamin D per cubic centimeter. Doses varying from 1 to 5 cc. have been used in twenty-four hours. The treatment has been observed to abolish the pain of iritis; rapidly rising temperatures reached their peak soon after midday, herpes zoster did not progress to vesicle formation and patients with general peritonitis looked well. It has also been used in severe burns for shock, in bronchopneumonia, in septicemia, in pernicious anemia with degeneration of the cord and in various nervous diseases. These vitamins should not be regarded as being strictly part of the fighting forces of the body at all. Rather they seem to give what one might call positive health to some of the body cells, enabling them to withstand the effects of infection. They are not anti-

toxic in the way of neutralizing the toxins, but they do seem to be able to render the cells more impervious to toxic effects and probably help to repair damage. If this is so, it is only natural that their sphere of usefulness should be wide.

Leptospirosis in Glasgow Tripe-Workers.—Stuart cites a case of leptospirosis, Weil's disease, in a tripe-worker and gives evidence of such infections having occurred in four of twenty-five other tripe-workers. Of fourteen rats caught in the building in which the cases occurred, eleven showed infection with *Leptospira icterohaemorrhagiae*. Evidence suggestive of *Leptospira canicola* infection has been found in one human case.

Vitamin C and Nitrogen Metabolism in Psoriasis Vulgaris.—Reiss investigated the excretion of vitamin C in psoriatic patients, the response of excretion of vitamin C after peroral and intravenous medication, the effect of vitamin C on basal metabolism, sulfur and nitrogen metabolism and the clinical effects of vitamin C on psoriatic lesions. There was a definite decreased excretion of vitamin C in his cases of psoriasis. It is all the more remarkable, because the daily intake was within fairly normal limits. The author cannot give an acceptable explanation of this depletion but believes that it is either destroyed by an infective agent of various origins supposed to be the cause of psoriasis or that the disturbed epidermal cellular metabolism in psoriasis demands a higher vitamin C intake. It is not impossible that in order to eliminate the waste products, which are accumulated in psoriatic scales, a higher amount of cevitic acid is required and the organism apparently cannot fulfil this increased demand with the supply of the ordinary diet. Unless some ability to synthesize vitamin C is assumed, difference between intake and output should be indicative of storage. A large amount is retained and only proportionally small quantities are excreted, which is a further proof of the depletion and of the high demand of cevitic acid in psoriasis. There does not seem to be any difference between the intravenous and peroral route of medication in the urinary excretion of cevitic acid. No definite conclusion can be made on the influence of vitamin C on basal metabolism. There was a definitely decreased excretion of sulfur, which can be increased by medication with vitamin C. Cevitic acid has little appreciable effect on nitrogen excretion. With the exception of two cases which cleared up with the ingestion of cevitic acid and which were observed before the metabolic studies were begun, no case which is concerned primarily with the effect of vitamin C on metabolism showed any clinical improvement. It may be possible that clinical improvement could be achieved by saturating the organism. There seems to be some kind of vicious circle between the offered vitamin C and its rapid destruction, in the solution of which may be found the key to the treatment of psoriasis.

Morphologic Types of Predisposition to Pulmonary Tuberculosis. A. Jacquelin and A. Opolon.—p. 545.

*Late Cardiac Disturbances After Electrical Accidents. C. Verdan.—p. 547.

Cardiac Disturbances After Electrical Accidents.—

According to Verdan, auricular fibrillation is a syndrome of multiple causation. After discussing predisposing and eliciting factors, he directs attention to the importance of electrical accidents in the etiology of auricular fibrillation. It is known that electric current may elicit ventricular fibrillation which results immediately in death, but it is established also that auricular fibrillation may follow immediately after an electrical accident. The author regards it as curious that in this century of electricity, in which electrical accidents are comparatively frequent, such cases are rare. In a review of the literature he cites the case of Jaksch-Wartenhorst and Rhil, in which the auricular fibrillation was detected by electrocardiographic registration immediately after the electrical accident. Other cases of auricular fibrillation after electrical accidents are those of Dick, of Laslett, of Hay and Jones and of Sigler and Schneider. Especial attention is directed to the studies of Jellinek, who differentiates between immediate and late cardiac disturbances. The author thinks that the late cardiac disturbances after electrical accidents deserve especial attention. He gives detailed histories of two interesting cases which have the following points in common: 1. At the time of the appearance of the first symptoms, both patients were young men of about the same age, 31 and 32 years, respectively. 2. In neither of them did the previous history reveal rheumatism, polyarthritis or febrile inflammatory diseases. 3. Neither of the two presented cardiac defects, especially mitral stenosis. 4. They did not have hyperthyroidism. 5. Neither of the two patients could state exactly when the first symptoms had disappeared. 6. The auricular fibrillation had existed for several years without modification, but it did not diminish the working capacity of the patients. 7. Both of the patients had sustained a typical electrical accident (shock of 500 and 220 volts, respectively, of an alternating current), before the appearance of the first symptoms. Since no other causes could be found, it is assumed that the cardiac disturbances are due to the electrical accidents. In view of the period of latency, however, which was especially prolonged in the second case, the connection is not absolutely certain. The author describes the history of a third patient with cardiac disturbances in whom the anamnesis revealed many minor and one rather severe electrical accidents. He admits that observations will be necessary to confirm or to contradict his view on the possibility of an etiologic connection between electrical accidents and auricular fibrillation. He says that just when this report was ready for the press a paper by Bruno Vogt appeared in the *Klinische Wochenschrift* (16:1671 [Nov. 27] 1937) on disturbances of the cardiac rhythm and anginal disturbances after an electrical accident. This case is interesting because it confirms Hüllstrung's observations on the elicitation of anginous disorders by electrical shocks.

40: 209-286 (April) 1938. Partial Index

Mixed Tumors of Palatine Arch with Particular Histologic Character. L'Hirondel and J. Leroux-Robert.—p. 226.

*Present Histologic Conception of Mixed Tumors of Buccal Cavity. J. Leroux-Robert.—p. 231.

Mixed Tumors of Buccal Cavity.—Leroux-Robert points

out that the stomatologist encounters tumors in the buccal cavity which are designated as "mixed." They are usually observed in the region of the soft palate or of the palatine arch. More rarely they are found on the internal surface of the cheeks or on the lips, only exceptionally on the tongue and still more exceptionally in the region of the sublingual glands. His material comprises 115 cases of mixed tumors of the cervicofacial glands (parotid, submaxillary, soft palate, palatine arch, lips, tongue, nasal cavity, lacrimal glands). Clinically they are mostly tumors that are well defined and well encapsulated. A number of these cases concern patients whose history could be followed for fifteen or eighteen years in the course of the successive relapses. The author analyzes the composing

elements of the mixed tumors: the epithelial elements and the interstitial stroma. Then he takes up the architectural classification of the tumors and finally he discusses the clinical and evolutive characters of these tumors. He concludes that the mixed tumors of the salivary glands are epithelial tumors to be placed in the group of epitheliomas of the glandular parenchyma. This conclusion was imposed by (1) the histologic characters of these tumors which, contrary to the classic opinion, are not tumors of multiple neoplastic strains but rather epithelial tumors which have individuality only because of the importance of modifications which the epithelial elements force the connective tissue to undergo and vice versa; (2) the clinical and evolutionary characteristics of these tumors, which behave like epitheliomas by their tendency to relapses in more than half of the cases, and by their capacity to form metastases. The author refrains from a detailed therapeutic discussion, regarding entirely the treatment of the tumors by radium, but he emphasizes a surgical factor. The mixed tumors must be removed as extensively as possible and not by simple enucleation of the tumor. When it concerns a salivary gland proper, the gland in which the tumor develops must be removed in its entirety.

Gastroscopy in Diseases of Blood. P. Chevallier and F. Moutier.—p. 935.

*Bone Marrow in Patients with Nephritis: Hemopoiesis and Definition of Nonprotein Nitrogen in Bone Marrow of Patients with Nephritis. G. Alexieff.—p. 972.

Question of Agranulocytosis Caused by Aminopyrine. E. Filo.—p. 996.

Bone Marrow in Nephritis.—Renal insufficiency, Alexieff says, leads to intoxication, which on the one hand becomes manifest in chemical disorders of the blood and on the other hand provokes a reaction of the hemopoietic organs, and the bone marrow in particular. It is necessary to differentiate between true and false anemia of nephritis. The latter depends on edema of the skin, cutaneous vascular spasms and chiefly on hydreemia, which is like an edema of the blood itself. Even if the cases of false anemia, determined by hydreemia, are excluded, it is still true that anemia exists in the majority of patients with chronic nephritis. This anemia of nephritis is not the result of a hemolytic process. In a minority of cases it develops as the result of a grave hematuria; in the majority of cases the anemia is the result of a deficient erythropoiesis in the bone marrow. The author decided to make an in vivo study of the bone marrow of nephritic patients. He studied the morphology of the bone marrow on dry smears colored by the method of Pappenheim (May-Grünwald-Giemsa). Simultaneously he determined the nonprotein nitrogen in the bone marrow and in the peripheral blood. The investigations were made on twenty-three patients, sixteen of whom had various renal disorders. Of these sixteen nephritic patients, thirteen presented anemia. Studies were made also on dogs with experimental uremia. On the basis of his clinical and experimental studies, the author concludes that: 1. Anemia of nephritic patients is a true anemia due to intoxication of the bone marrow by nitrogenous products. The degree of this anemia is found to correspond not with the azotemia of the blood but rather with the duration of the disease. The study of the bone marrow reveals a feeble regeneration of the normoblastic type which characterizes anhemopoietic anemias. 2. The leukocytosis, which is observed in nephritic patients, just as that of patients poisoned by mercury bichloride, is due to a pronounced regeneration of the myeloid tissue. 3. The number of blood platelets and of megacaryocytes (in the blood marrow), just as their morphologic character, does not show great modifications. The hemorrhagic symptoms that are observed in these patients are not at all dependent on a thrombopenia. 4. The bone marrow cannot be considered as a depot of nonprotein nitrogenous products. 5. Fluctuations in the nonprotein nitrogen content of the blood and bone marrow are about parallel. 6. The cases of intoxication by mercury bichloride are accompanied by a severe azotemia in the bone marrow. In the author's opinion this fact is explained in a satisfactory manner if it is admitted that the mercury bichloride produces a severe irritation of the bone marrow, which provokes a rise in the nitrogenous metabolism with increased formation of nonprotein products.

Effect of Pneumothorax on Contralateral Tuberculosis.

—De Luca followed the behavior of contralateral tuberculosis after establishment of unilateral artificial pneumothorax in ninety-nine patients suffering from bilateral pulmonary tuberculosis. The author concludes that unilateral artificial pneumothorax, done on the lung which is most intensely involved by tuberculosis, has a beneficial action on the pneumothoracized and the contralateral lung. The unsatisfactory results of unilateral pneumothorax in relation to lesions in the contralateral lung are due to pleural adhesions. The respiratory trauma at the point of insertion of the adhesion to the parenchyma of the lung is harmful and favors the evolution of tuberculous parenchymal lesions.

- Spirochetal Origin (Spirochaetosis icterohaemorrhagica) of Certain Fevers of Short Evolution Commonly Diagnosed as "Rheumatic Fever." C. Cantieri.—p. 79.
- *Specific Gravity of Urine Test for Functions of Kidneys. M. Sorrentino.—p. 83.
- Late Intracranial Hemorrhage from Trauma. C. Fucci.—p. 87.

Specific Gravity of Urine.—Sorrentino describes a technic for the examination of the function of the kidneys which he calls the test of specific gravity of urine. It consists in the determination of the volume and specific gravity of the urine that is eliminated in twenty-four consecutive hours. The patient, with an empty stomach, urinates at 8 in the morning on the day of the test. This specimen of urine is disregarded. After this the patient urinates at intervals of two hours. The volume and specific gravity of urine are determined immediately after each micturition. The patient voids the first two times while fasting. During the test the patient takes only one breakfast, one dinner and 1 liter of water. Breakfast is given at 12 noon. It consists of meat, bread, fruit and 1 liter of hypotonic water. Immediately after breakfast the patient goes to bed and lies there for four hours, after which he may get up and walk about. He has a dry dinner at 8 p. m. with some fruit but no soup, broth or water. The patient retires at 10 o'clock. All the urine eliminated between 10 p. m. and 8 a. m. of the following morning is put in a vessel and determinations are made as though for a single specimen. When the kidney has a normal capacity of concentration the urine reaches the greatest density of from 1.020 to 1.018. The oscillations between the greatest and lowest density are between 8 and 10 points. When there is insufficient renal concentration the greatest density is much lower than the foregoing figures, and the oscillations between the greatest and lowest densities are from 2 to 5 points. The greater the insufficiency of the kidney for concentration of urine the lower the figures of greatest density and the slighter the difference between the highest and lowest figures. In cases of hyposthenuria the figures of greatest density of the urine vary between 1.003 and 1.001, with slight oscillations between extremes. In moderate renal insufficiency the greatest density of urine is slightly lower than 1.018 and the oscillations between extremes are normal. In common chronic nephritis the changes are just the opposite. The author concludes that the test is simple and reliable. It is of value in the diagnosis of the origin of hypertension (arterial, renal or associated), the type of albuminuria and the intensity of chronic nephritis. The greatest value of the test consists in showing advisability or contraindications for immediate surgical intervention in renal and prostatic diseases. Hyposthenuria in nephrectomized patients as

well as in patients who are suffering from prostatic and bilateral renal diseases contraindicates an immediate surgical operation. The patients are in a condition of oliguria, and azotemia may easily develop if an operation is performed. It is advisable to prepare the patients for the operation, which will be performed when polyuria is reestablished.

Sulfur Metabolism in Children During Typhoid.—Biddau followed the behavior of sulfur in the blood of twenty-one children from 3 to 10 years of age in the course of typhoid. Cultures and blood serum tests gave positive results in all cases. The author found that during the febrile phase of the infection the metabolism of sulfur is altered. The oxidized fraction is slightly diminished, whereas the neutral fraction is much increased. The amount of total sulfur in the blood is slightly increased. The ratio between neutral sulfur and total sulfur in the blood is greatly increased. During convalescence the sulfur metabolism returns to normal. According to the author the changes of the sulfur metabolism in the course of typhoid are due to the following factors: (1) insufficient supply of exogenous sulfur because of lack of appetite of the patient and disturbances of absorption of the digestive tract, (2) increased disintegration of cellular proteins and (3) pathologic involvement of the liver, the adrenals and the spleen with consequent dysfunction of the structures to carry on the processes of fixation and oxidation of sulfur.

Eclampsia Allergy.—Wepler observed, in the peripheral arteries of the lung of an infant of 3 days, proliferation of the endothelium and secondary fibrinous thrombi. He says that these processes correspond to the vascular changes that are observed in allergic diseases. He regards the severe eclampsia in the mother as the cause of the changes in the lung of the infant. This observation is further corroboration of the theory that eclampsia is an allergic disorder.

Cutaneous Temperature in Different Diseases.—Scheurer and Müller investigated whether organs with inflammatory processes influence the temperature of the skin above them. They made measurements on more than 100 bedridden patients by means of the thermo-element of Büttner. The instrument was applied to the region immediately after the area was uncovered and the temperature was read on the galvanometer. In measurements on twenty-seven patients with pulmonary tuberculosis, the authors discovered nearly always an increase in temperature on the diseased side, when the process was an exudative or an exudative-cavernous one. As the process

exacerbates, the increase in the cutaneous temperature becomes more noticeable. Cirrhotic processes seem to be without influence on the cutaneous temperature. In lobar pneumonia as well as in bronchopneumonia, the temperature does not show a uniform behavior. However, in new infiltrative processes which are not too far from the thoracic wall, the temperature is nearly always increased. The authors admit that in thoracic processes the measurement of the temperature, although of theoretic interest, is of slight practical value, because the diagnosis of these disorders is possible by roentgenoscopy. In articular diseases, however, the measurement of the cutaneous temperature is of considerable significance. Previous investigators had proved that in acute arthritis, as in tuberculosis and syphilis of the joints, the cutaneous temperature is increased, whereas in chronic articular rheumatism and arthritis deformans it is generally reduced; moreover, that an increase in cutaneous temperature over a joint in cases of chronic polyarthritis often indicates an exacerbation. The investigations made by the authors in articular disturbances revealed practically the same. They think that in articular diseases the measurement of the cutaneous temperature is a valuable aid for the diagnosis, the prognosis and the evaluation of the curative process. The same statement can be made about a number of diseases of the vascular system such as thrombophlebitis and arteriosclerotic gangrene. In inflammations in the abdomen the evaluation of the cutaneous temperatures would be of great importance, but the cited observations indicate that in these cases the behavior of the cutaneous temperature differs considerably. Nevertheless, the noticeable increase in the cutaneous temperature in cases of paranephric abscess, adnexitis, parametritis, dropsy of the gall-bladder and several other disturbances show that the measurement of the cutaneous temperature is a method which, together with other methods of examination, can be of value in the diagnosis of somewhat obscure cases.

Orally Administered Sulfur.—Kühn says that the wide distribution of sulfur in the organism indicates the important role of sulfur in the life processes. The investigations reported in this paper were aimed to determine to what extent the metabolism can be influenced by the oral administration of sulfur. A sulfur preparation susceptible of resorption and containing sulfur in a reduced form was given in different doses to persons who were free from metabolic disturbances. The urine was examined for specific gravity, nitrogen, carbon, sodium chloride and the various sulfur fractions. Bickel's C:N quotient and the elimination of sulfur (particularly neutral sulfur) were taken as indicators of metabolic changes. It was found that the sulfur preparation increased the intermediate metabolism. In this connection the author points out that the same action had been noted by other investigators in the parenteral administration of sulfur.

Heredity in Progressive Muscular Dystrophy.—Kostakow and Bodarwé point out that, whereas most investigators agree that progressive muscular dystrophy is hereditary, the mode of transmission is still a disputed problem. On the basis of a careful study of the literature and of their own investigations on several groups of families, they conclude that progressive muscular dystrophy is always hereditary. Mutations of the hereditary factors of past generations is the pathogenic basis. The hereditary transmission is not uniform. This lack of uniformity is due to the fact that in addition to dominant genes recessive genes have a part. There are two genotypically different forms of progressive muscular dystrophy, an infantile and a juvenile type, both of which are hereditary. The authors show six genealogic trees and list the characteristics of the persons indicated in the diagrams. In two of the family groups, the hereditary transmission was sex linked and recessive and in the four other groups the transmission was of the simple recessive type. In one genealogic tree with recessive heredity a marriage between blood relatives was detected in the ascendancy. In this connection, the authors direct attention to the significance of marriages among relatives for the development of progressive muscular dystrophy from a recessive hereditary factor. In the genealogic trees with the sex-linked recessive heredity the patients are mostly of the infantile type with pseudohypertrophy; in those with the simple recessive heredity there are patients with the infantile and juvenile forms. The

causes of death in the fatal cases were usually disorders of the respiratory organs and in those who survived there was likewise a great susceptibility for the diseases of the respiratory organs.

Quinine-Calcium in Pneumonia.—Ott reports his experiences with quinine-calcium treatment in 125 cases of pneumonia. Thirty-seven of the patients were children less than 5 years old, twenty-three were between 5 and 15 and the others were adults. The children received daily from 1 to 5 cc. of the quinine-calcium according to age; the adults were given 10 cc. daily. The total number of injections was between two and six. In children the mode of injection was always intramuscular. In adults it was at first intramuscular but later intravenous. Discussing the results of the quinine-calcium treatment, the author admits that the main advantage of this treatment, the shortening of the disease process, was realized in only a few cases, but in only twelve of the cases was the treatment begun before the third day of the disease. Although the quinine-calcium therapy did not fulfil all the expectations, the author recommends this treatment particularly at the onset of pneumonia.

*Little Known Cause of Pains in Throat. E. N. von Oettingen.—p. 413.

Pains in Throat.—Von Oettingen directs attention to a comparatively rare cause of recurrent pains in the throat, which readily escapes the ordinary examination and therefore remains often unrecognized. He relates the clinical histories of two patients. The first patient was a man aged 32 who for the last two years had had a hard formation behind the right palatine tonsil, which caused difficulties during swallowing, speaking and turning of the neck. Moreover, the patient complained of increased salivation, a feeling of tension in the right side of the inferior maxilla and tinnitus aurium on the right. Treatment had so far been unsuccessful. On the basis of a thorough examination and of roentgenoscopy, the disorder was finally diagnosed as abnormal prolongation of the styloid process. Following tonsillectomy the styloid process was exposed and a piece 2 cm. in length was removed from the lower end. The patient recovered and the symptoms disappeared. After reporting a second case of abnormally long styloid process, the author says that these cases frequently are not correctly diagnosed because in case of obscure disorders of the neck the examiner neglects the palpation of the oral cavity and the roentgenoscopy of the upper cervical region. The author explains the pathogenesis of such anomalies on the basis of the paleogenesis of the second branchial arch. From the inspection of 500 roentgenograms of the otologic clinic he draws conclusions about the incidence and extent of ossifications in that portion of the former branchial arch which is designated as Reichert's cartilages. His observations indicated that remnants of the hyoid arch can be expected in about 10 per cent of the cases. This percentage is considerably below that of Dondoli (25 per cent). The cause of this difference is still obscure, but the author thinks that racial factors may have a part.

Chronic Arsenic Intoxication by Grape Parasiticides.—Schöndorf describes observations on a number of patients whose disorders were found to be the result of chronic poisoning with arsenic. Following a report of the clinical histories of twelve patients, he summarizes the symptomatology of the arsenic intoxication. The hyperkeratosis and melanosis were the

most constant and the most noticeable symptoms. The hyperkeratosis involves the inner surface of the hands and the soles of the feet. The keratotic areas are rough and fissured and a large number of small, hard, wartlike or stalactite-like elevations are visible. The melanosis is found chiefly on the trunk, particularly in the lumbar, inguinal and axillary regions. It appears as a dark brownish pigmentation interspersed with streaks that are free from pigment, so that a reticular outline is the result. In two cases, dark pigmented foci were observed also on the face. Partly as the result of a true polyglobulism and partly caused by a dilatation of the capillaries, the face shows an intense reddishness. This, together with the melanosis, gives the patients such a characteristic appearance that the diagnosis can frequently be based on it. Occasionally, papular eruptions appear on the face. On the whole, the skin is rather dry and atrophic. In the majority of the cases a hepatic impairment was noticeable. The damage to the liver is the most serious symptom of arsenic poisoning. The fatal termination of one of the cases was in the final analysis due to a failure of the hepatic function. Examination of the gastric juice revealed in the majority of cases subacidity and a high leukocyte content indicative of a gastritis. The majority of patients had signs of irritation in the upper and lower air passages. Polyneuritic symptoms were observed in four of the patients. For therapy, the author says emphasis was put on eliminating measures such as sweating cures, wet compresses and baths. When hepatic impairment had been detected, the treatment was the same as in other types of hepatic cirrhosis. Attention was given also to the proper evacuation of the bowels and adsorbents were given. The nature of the disorder was explained to the patients, and efforts were made to prevent further intake of arsenic. The majority of the patients were persons who worked in vineyards and who handled parasiticides containing arsenic. Four of the patients did not handle the arsenical parasiticides, but they too lived in the vineyard region and it is suggested that arsenic in the dust or a grape drink might be responsible. It is probable that an individual hypersensitivity to arsenic has a part in the pathogenesis of the arsenic intoxication because, taking into consideration the extensive use of arsenical parasiticides, the disorder would be more frequent if such was not the case.

Acute Nicotine Intoxication.—Kobro reports the clinical history of a youth, aged 18, a gardener, who developed acute nicotine poisoning after spraying plants in a closed greenhouse with a solution of nicotine sulfate. After spraying 400 liters of a 0.2 per cent solution of the nicotine sulfate in the course of several hours, during which he had inhaled the nicotine-charged air, the patient showed signs of intoxication. There were nausea, vomiting, convulsions and cyanosis. A retardation in the pulse frequency was soon followed by a tachycardia; moreover, there were mild temporary hypertension, increased vasomotor irritability, weak or abolished tendon reflexes, anisocoria and changes in the blood. Following hospitalization the symptoms gradually subsided and the patient was discharged after two days. Discussing the probable mode of development of the different symptoms, the author cites earlier animal experiments and stresses the part played by epinephrine and the suprarenals in the development of the nicotine intoxication.

Vitamin B₁ and Carbohydrate Metabolism.—Gottlieb directs attention to earlier reports on the great importance of the vitamin B complex for the carbohydrate metabolism. Among others, he cites Funk's observation that the symptomatology of beriberi can be exacerbated by the increased intake of carbohydrates and improved by the restriction of the carbohydrate intake. Vogt-Mjller found that the vitamin B₁ requirements in beriberi are in direct proportion to the ingested quantity of carbohydrates. Moreover, excessive intake of sugar has been found to produce clinical pictures similar to the picture of beriberi. After citing animal experiments carried out by a number of investigators the author says that, in view of the disturbances in the carbohydrate metabolism during B avitaminoses, studies have been made to investigate whether vitamin B influences the carbohydrate metabolism in diabetes mellitus. He reviews some of the former investigations and then describes his own studies on the effect of injections of thiamin chloride on diabetic sub-

jects and on persons without metabolic disorders. Investigating the effect of thiamin chloride on the fasting blood sugar of persons with and without diabetes mellitus, he observed a slight reduction in the blood sugar. Further he studied the influence of thiamin chloride on the course of the blood sugar curves of healthy and diabetic persons after dextrose tolerance tests. He observed an increase in the tolerance in the majority of cases. In case of insulin tolerance tests on healthy and diabetic persons, the action of thiamin chloride on the course of the blood sugar curve consisted in an intensification of the insulin action. The author observed further that the administration of thiamin chloride increases the hydrochloric acid secretion of the stomach. He discusses the possibility of a modification of the carbohydrate metabolism by vitamin B₁ by way of the sympathetic nervous system.

Insulin Shock Therapy of Schizophrenia.—Krasnushkin and Khanlaryan point out certain antagonisms between schizophrenia and a number of diseases and pathogenic factors. There is some antagonism between acute infectious diseases and schizophrenia, and on the other hand a tendency to symbiosis with chronic diseases. A pyknic-thymic constitution exhibits an antagonism toward schizophrenia, but the shock producing factors manifest this antagonism in the highest degree. Among these the authors mention physical trauma to the brain, epileptic attacks, strangulation, psychic shock and the agonal state. The convulsion therapy of Meduna and the insulin therapy of Sakel utilize these antagonistic shock producing agents, the first by provoking epileptic attacks with the aid of camphor or metrazol, the second by inducing hypoglycemic shock. The glycopenic states in schizophrenic patients are complicated by certain peculiar psychotic manifestations which in themselves are of a favorable prognostic significance. Among these are a sense of euphoria, syntonía, self analysis and criticism and the disappearance of the constant schizophrenic symptoms. Among other manifestations are motor stimulations, maniacal states, occasionally depressive and hysterical states, and exacerbations of schizophrenic symptoms. According to the authors these manifestations, without actually reaching a comatose or precomatose state, give a favorable prognosis. The authors regard the technique of application of this method entirely safe and the benefits to be derived from it so decided as to consider it entirely permissible. The mortality from the application of the method in the western European clinics amounted to 1 per cent. It is, however, important to bear in mind certain contraindications to the treatment, such as diseases of the cardiovascular system, particularly arteriosclerosis, active pulmonary tuberculosis and nephritis. The authors have treated fifty-two patients by the method, most of them early cases up to one and one-half years in duration, and have noted a high percentage of recoveries and remissions, particularly in the early cases. The most striking results were obtained in paranoid types. The authors observed in most of their cases the development of prolonged (several weeks) hypomaniacal states, exhibiting all the features of manic-depressive insanity, as a transitional phase toward a favorable remission. The patients, at the same time, manifested an improvement in the physical state and a shift toward the physical characteristics of the pyknic constitution. With the aid of orthocardiographic studies, Dr. Lakosin of their clinic was able to demonstrate the change from the vertical position of the heart characteristic for schizophrenia to the dorsal, characteristic of a pyknic constitution. The authors believe that the effective action of insulin therapy is due to two antagonistic factors: (1) the shock-inducing effect of glycopenic attacks, resembling those of epilepsy, and accompanied by anoxemia of the brain cells as it occurs in strangulation, and inducing in its deep states a condition of coma nearing the agonal state, and (2) by stimu-

lation of elements antagonistic to circular constitution, a fact which explains the greater number of remissions in paranoid types, since these exhibit more ingredients of that constitution than other forms of schizophrenia.

Diagnosis of Early Hyperthyroidism. B. Z. Broder.—p. 123.
*Acidophilus Milk Therapy of Colitis. M. G. Gorin and D. Ya. Rosenberg.—p. 131.

Lobeline Method for Determining Velocity of Blood Circulation.—According to Evzlina, pharmacologic studies established that the stimulating effect of lobeline on the respiratory center is due to its action on the carotid sinus. She performed 140 determinations of the velocity of circulation by introducing into the cubital vein the contents of one ampule (0.003 cc.) of lobeline. This was done on an empty stomach, from one to two seconds being taken for introduction of the drug. This was followed by a reaction consisting of a deep inspiration followed by coughing, which persisted for from five seconds to two minutes. No other phenomena were noted. On the basis of her experience with the method in various diseases as well as in healthy persons, the author concludes that slowing of the velocity of blood circulation constitutes one of the earliest signs of circulatory insufficiency. The method alone cannot be regarded as determining the existence of a failing circulation; the latter is arrived at only after a complex study of all the hemodynamic factors. The lobeline method is to be preferred to all others because of its objectivity, a definite rapidly disappearing reaction, absence of any unpleasant concomitant manifestation, the possibility of repeating the determination within a short time without any harm to the patient, and the uniformity of the results. Patients with a decompensated cardiovascular system exhibit a definite slowing of the velocity of circulation. Successful digitalization is followed by a corresponding increase in the velocity of circulation.

Acidophilus Milk Therapy of Colitis.—Gorin and Rosenberg treated one group of seven patients with chronic diarrhea on the customary antidiarrhea diet for from seven to ten days, after which, if the symptoms were not modified, they added to the diet acidophilus milk. This was taken in three equal portions after meals in doses beginning with 100 cc. daily and increasing by 100 cc. daily until 500 cc. was taken. The same therapy was applied to another group of sixteen patients with the difference that the diet was an ordinary bland sparing diet and not a definitely antidiarrhea diet. The diet alone brought about an improvement in only one case of the first group. After the acidophilus milk therapy, five of the group had formed stools. Diet alone had no effect on the intestinal flora. On the acidophilus milk therapy a part of the patients exhibited a change from a gram-negative to a gram-positive or a mixed flora. The acidophilus milk therapy in the second group of sixteen persons resulted in a clinical cure in nine, improvement in three and insignificant improvement in four. On the indifferent diet a change in the microflora, in twelve investigated cases, took place in four; in one it changed to a gram-positive and in three to a mixed flora. When acidophilus milk was added the flora changed from a gram-negative to a gram-positive in five, became mixed in five and was unaltered in two. Patients who did not exhibit satisfactory improvement from the combination of the acidophilus milk and diet therapy were placed on "acidophile days." The method consisted of keeping patients in bed for from two to three days, all food being withheld except acidophilus milk in amounts of from 1 to 1.5 liters a day. The combination of starvation with the feeding of the acidophilus milk was much superior in its effect to other methods. The authors feel that the element of starvation was an important factor in the results obtained. Diarrhea disappeared and the stools became formed in 75 per cent after the first day, in 82 per cent after the second and in 91 per cent after the third. They feel that "acidophile days" present an advantage over the fast-

ing days advocated by von Noorden because they avoid the loss of calcium, obviate the necessity of subcutaneous injections of nutritive solutions and furnish from 60 to 75 per cent of metabolic needs, while the shift within the intestinal flora to acidosis creates unfavorable conditions for the growth of the putrefactive micro-organisms.

Thrombocyte Count in Anemia.—Heinild made thrombocyte counts in twenty-six cases (seven of pernicious anemia, five of hepatic cirrhosis or hepatic atrophy, seven of achyl-anemia and seven of cancer of the digestive tract). In all cases of pernicious anemia the thrombocyte values were definitely reduced and sometimes extremely low. In all cases of hepatic cirrhosis the thrombocyte count was also below normal; in one instance, in which the picture agreed with that of hepatic atrophy (Geil and Jørgensen), an extreme thrombopenia was demonstrated during three months. In achyl-anemia the blood platelet values were normal. Of the cancer patients five had a definitely increased thrombocyte count and two a normal count; necropsy was performed in the former, while in the latter diagnosis was made after roentgen examination and operation, respectively, which might perhaps indicate that a certain time is needed for the development of thrombocytosis.

Treatment of Pyelitis with Granulatum Calcii Amygdalatis: Report from Practice. E. A. Kirketerp.—p. 347.

Infectious Mononucleosis and Meningo-Encephalitis.—In the first of the five cases of infectious mononucleosis described there were signs of meningitis on admission. Hence spinal fluid was examined in the other four cases, although no clinical signs of any infection in the central nervous system were seen on admission. The first four patients all gave positive agglutination in the blood with sheep blood corpuscles and growth of *Listeria* in the cerebrospinal fluid. In view of these cases Schmidt and Nyfeldt suggest that examination of the cerebrospinal fluid would be advisable in patients with infectious mononucleosis, especially considering the demonstrated late infection of the central nervous system. Treatment should accordingly be extended beyond the usual clinically demonstrable infectious stage, because of possible sequels in the form of chronic changes due to the involvement of the central nervous system in infectious mononucleosis.

EXCRETION OF SULFANILAMIDE

J. D. STEWART, M.D.

G. M. ROURKE, B.A.

AND

J. G. ALLEN, M.D.

BOSTON

The drug para-amino benzene sulfonamide, or sulfanilamide, and its related compounds is in wide use at the present time in the treatment of certain infections. Its usage rests largely on an empiric basis, and much remains to be learned about the bacteriologic and pharmacologic aspects of the drug. The present study is concerned with factors governing the excretion of sulfanilamide when administered in treatment.

In a group of patients without cardiovascular, hepatic or renal disability, and without infection, a measured amount of sulfanilamide was given daily at six hour intervals for from three to six days. With each dose of sulfanilamide three fourths as much sodium bicarbonate was given. Complete collections of urine were made in each case and an aliquot sample of the daily total was used for determinations. The intake of fluid was carefully measured, and the patients drank as desired. The regular hospital house diet was taken during the study. Venous blood was drawn under oil without stasis at the beginning and at appropriate intervals during the course of the study, analyses being made for nonprotein nitrogen, serum bicarbonate, serum chloride, oxygen capacity and sulfanilamide content of whole blood. At the end of from three to six days the administration of sulfanilamide was stopped, the last dose being given at 3 a. m. Six hours later the study of urinary excretion in two periods under fasting conditions was begun. During the first period of two to three hours no fluid was taken. During the second period of similar duration the patient drank all the water he could take without discomfort, the amount being in the different cases from 500 to 1,100 cc. Thus the urinary excretion of sulfanilamide in two periods was determined, in the second period there being a larger urine volume in consequence of water drinking. Blood analyses were made before the first period. It was found that the sulfanilamide level in the blood did not vary significantly if determined again at the end of the first period; hence this determination was usually not repeated. Daily collection of urine was continued until only traces of sulfanilamide were recoverable in the samples. The fall in blood concentration also was studied.

The cases were carefully studied for complications, but this phase of the subject will not be discussed here. It should be said however that, although all the patients became mildly cyanotic, none showed any serious complication or distressing symptoms.

Standard analytic procedures were used. Sulfanilamide in both its free form and its acetylated or conjugated form was determined in blood and urine by the technic developed by Marshall.¹

PRESENTATION OF DATA

In table 1 are shown data on the total recovery of sulfanilamide in the urine during the study, the average being 93.2 per cent. In case 6 loss probably occurred through a freely draining cholecystostomy wound. In case 7 a rather copious diarrhea did not result in loss of sulfanilamide. Since the urine still contained small amounts of sulfanilamide in these cases at the end of the study, it is possible that an even more complete recovery of the administered drug could have been made.

In the chart are shown graphically data obtained in a typical case (case 5). The total recovery of sulfanilamide in the urine was 97 per cent. The duration of the study was eight days, the sulfanilamide being taken for the first five days. In three days equilibrium had been established between intake and output of the drug, and the blood concentration stabilized. The rapidity with which sulfanilamide is eliminated from the body through the urine is well shown.

In table 2 are shown data demonstrating the effect of water diuresis on urinary excretion of sulfanilamide. Clearances in cubic centimeters of blood per minute are computed for free and conjugated sulfanilamide for first the period of water abstinence and then of water drinking. The percentile change in rate of excretion of urine and of sulfanilamide is expressed for each case, and the averages for all cases are also given.

Table 3 contains data on concentrations of conjugated, free and total sulfanilamide in blood and urine during the period of moderate reduction in rate of formation of urine resulting from abstinence from water.

COMMENT

The high recovery of sulfanilamide in the urine shown in table 1 demonstrates the accuracy of the analytic technic in convincing fashion. The great importance of the kidney in dealing with the drug is apparent. It is possible to infer what clinical experience has already taught: sulfanilamide must be used cautiously and in smaller doses in the presence of renal disability. The completeness of absorption of sulfanilamide from the gastrointestinal tract and negligible excretion in the feces, even with diarrhea, is apparent.

1. Marshall, E. K., Jr.: Determination of Sulfanilamide in Blood and Urine, *J. Biol. Chem.* **122**: 263 (Dec.) 1937.

Another point of practical significance is the variability of blood level in different patients resulting from similar doses of the drug per pound. The need for doing frequent blood determinations in patients under intensive therapy is clear.

In considering the clearance data in table 2, the much more rapid clearance of conjugated sulfanilamide than free sulfanilamide is interesting. The exact meaning of this observation is not clear. The site in the

body at which acetylation of sulfanilamide takes place is as yet unknown. Were the process carried on in the kidney, a discordantly high clearance computation might result. On the other hand, since acetyl sulfanilamide is a quite different molecule from para-amino benzene sulfonamide, its rate of reabsorption in the renal tubules may be much slower, from which a more rapid clearance would result.

Average percentile change.....			+116.8%	+30.3%	+22.5%	

The rate of secretion of urine and clearance rate in each case are given first for the period of water abstinence and then for the period of water drinking. Percentile change with diuresis is recorded in each case. Clearance values are given as cubic centimeters of blood cleared per minute.

Diuresis results in an increased rate of excretion of both free and conjugated sulfanilamide, though the increase is not proportional to the increase in rate of the formation of urine. On this point our conclusion checks with that reached by Marshall and his collabora-

tors.² This brings out that it is more difficult to maintain a high blood concentration of sulfanilamide on a given dosage if the volume of urine is large. However, in view of the great importance of the kidney in affording the sole exit of the drug from the body, an abundant volume of urine seems desirable while the drug is being taken. Furthermore, a generous intake of fluid is usually indicated in treating the infection for which sulfanilamide is given.

No definite correlation between clearance rate of either free or conjugated sulfanilamide and blood concentration is discernible. We cannot agree with Marshall that the amount of the acetyl derivative excreted seems to depend on the amount present in the blood.¹ The clearance rate seems to depend a good deal on the particular renal response of the individual

to the drug, thus making for variability and indicating again the need for frequent determination of blood concentrations in clinical usage.

A question might be raised about the method of calculating clearances in this study. As previously noted, in several instances blood concentrations of sulfanilamide were determined not only at the beginning of the period of water abstinence but again at the end, before water drinking began. No significant difference was detectable. In several clearance studies, not under discussion here, the level of sulfanilamide in the blood was determined at the beginning of the period of water abstinence, at the beginning of the period of water diuresis immediately following the first period, and at the end of the period of water diuresis. No appreciable difference in blood concentrations was observed, although the patients under study had blood concentrations of less than 10 mg. per hundred cubic centimeters. We feel that in the present study clearance computations would not have been significantly altered if based on terminal as well as initial blood concentrations, though such a method is preferable.

The data in table 3 relate to a point of considerable importance. While collecting urine for clearance determination in case 4 during the period of water abstinence it was noted that a precipitate was forming in the indwelling catheter. Studies on this sample of urine showed that sulfanilamide, chiefly in the acetylated form, was crystallizing out in the indwelling catheter. The solubility of sulfanilamide in water at

2. Marshall, E. K., Jr.; Emerson, Kendall, Jr., and Cutting, W. C.: The Renal Excretion of Sulfanilamide, *J. Pharmacol. & Exper. Therap.* 61: 191 (Oct.) 1937.

room temperature is less than 0.8 per cent, while at body temperature it is only about 1.1 per cent.³ Acetylated sulfanilamide we find considerably less soluble.⁴ Urinary concentrations were in these ranges in the cases under study. No data on solubilities of free and acetylated sulfanilamide in urine are available, but in several instances we have observed precipitation of acetylated sulfanilamide in urine at room temperature soon after collection. Urine at body temperature would certainly have greater power to hold the drug in solution, but nevertheless the possibility of stone formation in the urinary tract or blockade of renal tubules, where large doses of the drug are given and urine volume is small, seems real. This subject is being studied further.

SUMMARY

1. Recovery of administered sulfanilamide has been studied on a quantitative basis in patients without cardiovascular, renal or hepatic disease and without evidence of infection.

2. Rates of clearance through the urine of conjugated and free sulfanilamide of the blood have been determined.

3. The effect of water diuresis on rate of clearance of conjugated and free sulfanilamide has been investigated.

Sulfanilamide balance study in case 5. IS, sulfanilamide intake in grams per day; US, sulfanilamide content of urine in grams per day; IU, daily urine volume in liters; BS, total sulfanilamide concentration of whole blood in milligrams per hundred cubic centimeters plotted on the ordinate scale.

4. Concentrations of conjugated and free sulfanilamide in blood and urine during a period of water abstinence have been noted.

CONCLUSIONS

1. In man sulfanilamide is excreted almost entirely by the kidneys, in either the free or the conjugated form.

2. The concentration of free and conjugated sulfanilamide in the blood resulting from a given per pound dosage is quite variable in different individuals; hence the importance of frequent determinations of blood level during intensive therapy with the drug.

3. After sulfanilamide has been stopped the drug is rapidly eliminated from the body, provided renal function is normal and urine volume adequate.

3. Allport, N. L.: Para-Amino Benzene Sulfonamide. *Quart. J. Pharmacy & Pharmacol.* 9: 560 (July-Sept.) 1936

4. Unpublished data.

4. The concentration of conjugated sulfanilamide in the blood is much lower than that of the free sulfanilamide.

5. The rate of clearance of conjugated sulfanilamide is greater than that of free sulfanilamide.

6. Water diuresis increases the rate of urinary excretion of both forms of the drug.

7. The precipitation of excreted sulfanilamide in urine at room temperature has been demonstrated, suggesting the possibility of formation of stones in the urinary tract should urine volume become too small during sulfanilamide therapy.

USE OF SULFANILAMIDE AFTER TRANSURETHRAL PROSTATECTOMY

HOWARD J. GAUDIN, M.B.

HARRY A. ZIDE, M.D.

AND

GERSHOM J. THOMPSON, M.D.

ROCHESTER, MINN.

The successful results that have accrued from the use of sulfanilamide in the treatment of infections of the urinary tract have prompted a survey of its utility in postoperative management of cases in which transurethral prostatic resection has been performed.

At least half of the persons presenting themselves for this operation have grossly infected urine. Only rarely do we endeavor to treat such infections prior to operation. Postoperative febrile reactions which may be traced to such infections occur infrequently in our cases and we believe that the offending bacterial organisms responsible in cases manifesting febrile reactions were probably introduced at operation and are not strains of bacteria previously harbored by the patient.

The study promised to be attractive because it was of a group of persons of the same sex, of approximately the same age, and all suffering from an obstructive lesion which gave rise to a similar sequence of clinical and pathologic events. The number of patients was sufficient to group into a control series and an experimental series, each to receive substantially identical treatment with the exception of the urinary antiseptic concerned.

The average period of postoperative hospitalization of the patients was five days and therefore it was decided that specimens of urine should be collected for examination at the time of operation and on the fifth postoperative day. Administration of the drug was begun on the morning of operation and was continued until the fifth day after operation.

COLLECTION AND BACTERIOLOGIC STUDY OF THE URINE

Each specimen of urine was obtained by catheterization under aseptic technic on the first and fifth days. The specimen was kept in the ice box until cultures were taken from four to six hours later. After the sample of urine had been mixed thoroughly, seedings were made on the surface of blood agar plates; these were incubated for twenty-four hours at 37.5 C. Subsequently, smears of the colonies growing on the plates were made and were stained by Gram's method and the results were recorded under the three broad headings

of gram-negative organisms, streptococci, including diplostreptococci, and micrococci, including staphylococci.

ADMINISTRATION OF SULFANILAMIDE

Every other patient admitted to the hospital was given the drug, and the alternate patients were used as controls. Discrimination was not made as to which patients should receive sulfanilamide. The dose ranged

Streptococci	32	23	12
Micrococci	30	34	31

between 45 and 60 grains (3 and 4 Gm.) daily, and the majority of the patients receiving this medication also were given a similar amount of sodium bicarbonate. No effort was made to establish a urine of a particular hydrogen ion concentration.

Because of nausea, cyanosis, skin reactions and even low grade fever, it was necessary to discontinue administration of the drug in nine cases. We present data on 100 patients who received sulfanilamide and an equal number, the control group, who received no urinary antiseptic whatever. We have available for comparison the bacteriologic observations in a similar group of 200 cases of transurethral prostatectomy compiled by Thompson¹ in 1934.

Table 1 brings out the close similarity as regards both the number of specimens of urine infected and how these infections behaved during the stage of post-

TABLE 2.—Summary of Bacteriologic Observations

operative hospitalization. Further, the types of organisms found in the series of 1934 were substantially as frequently encountered then as in 1937.

The sulfanilamide series brings out two apparent changes that we will mention at this time. First, there seems to be some general bactericidal action directed toward those organisms originally present in the urine. Second, a greater percentage of initially "sterile" urines remain culturally negative.

To proceed with a general survey of the results of administration of sulfanilamide on the urine, table 2 illustrates the infected (culturally positive) and the sterile (culturally negative) specimens of urine and their behavior during the course of the experiment.

Table 2 shows that an equal number of patients have infected urine initially in the respective groups. Five days later, however, among those patients receiving sulfanilamide, there is a drop in the percentages of infected specimens of urine and a larger number of uninfected specimens remain "sterile."

At this point we should discuss two important facts brought out by the two tables. First, in table 1, as indicated already, there seems to be some general bactericidal action directed toward those organisms originally present in the urine. A consideration of side headings 3, 4 and 5 shows that this does not seem to be true of additional organisms that have become established in the urine following operation. There is no significant difference in the percentages of these newcomers in the control series as compared with the sulfanilamide series.

There occur to us two possible explanations: 1. The additional organisms are contaminants. This we cannot believe, because the organisms now in the fifth day

TABLE 3.—Organisms Present in Urine on Fifth Day

	Control Series, per Cent	Sulfanilamide Series, per Cent
Organisms present on culture on fifth day:		
Gram-negative bacteria	34	16
Streptococci	23	12
Micrococci	34	31
Uninfected urine, became infected with:		
Gram-negative bacteria	35	18
Streptococci	32	20
Micrococci	46	58

urines were found in numbers easily demonstrated by Gram's stain of the urinary deposit, thus excluding the probability of their being contaminants introduced at the time of collection of these samples. 2. On the other hand, we might postulate that this drug acts not only as a bactericidal agent alone but also in some way reinforces the mechanism of immunity operating against chronic infection. The new invader, introduced at the time of operation, has not had time, within the limits of the experiment, to call forth a defense reaction on the part of the host and therefore it has only the bactericidal action of the drug to contend with. Clinical experience in the management of urinary infections would lead us to believe that administration of sulfanilamide is frequently followed by a more dramatic improvement in the chronic infection than we observe among cases of acute infection. The mechanism of operation of sulfanilamide as yet is unsettled. The hypothesis that it acts by stimulation of some mechanism closely related to the natural immunologic defenses of the subject has been expressed by many writers, particularly those in England and on the continent of Europe. Our evidence seems to confirm this hypothesis.

In table 2 the second item might indicate that sulfanilamide inhibits establishment of organisms in the urinary tract. This, however, would be an erroneous conclusion as reference to table 1 demonstrates. It is not necessarily specimens of urine from the same

1. Thompson, G. J.: The Prevention of Complications of Transurethral Prostatic Resection, Urol. & Cutan. Rev. 38:847-851 (Dec.) 1934.

patient, found to be infected on the day of operation, that we find infected on the fifth postoperative day.

The survey, up to the present, would indicate that a group of these patients, as a whole, would benefit from routine administration of this particular urinary antiseptic. It behooves us, therefore, to study the more detailed results of this therapy. In table 3 an analysis of the type of organisms present on the fifth day is presented.

The results of the cultures of these fifth day specimens would indicate that the effect of sulfanilamide is directed toward both gram-negative bacteria and streptococci and that the efficacy of this antiseptic in suppressing both of these organisms is about the same. Micrococci were found in about a third of the specimens examined irrespective of sulfanilamide.

Furthermore, micrococci found in the urine on the fifth postoperative day were not found in the urine prior to operation in 79 per cent of the sulfanilamide series and in 71 per cent of the control series. So far as these bacteria are concerned, they appear quite unaffected by administration of sulfanilamide. In the specimens of infected urine obtained five days after operation that were found to harbor micro-organisms not demonstrated in cultures of urine obtained on the day of operation, bacteria were demonstrated as shown in table 4, which gives the relative frequency with which these new invaders occurred in specimens of urine collected on the fifth postoperative day.

TABLE 4.—Frequency of New Invaders Present in Urine on Fifth Postoperative Day

Organisms	Control Series, per Cent	Sulfanilamide Series, per Cent
Gram-negative bacteria	45	57
Streptococci	84	73
Micrococci	71	79

We can only conclude from these results that strains of organisms gaining foothold after operation are not influenced by administration of sulfanilamide, although it would seem, from earlier tables, that the actual number of infected specimens is decreased following its administration.

A discrepancy was found between cultural results and microscopic examination of the sediment obtained by centrifuge in a number of the specimens. Pus cells in these specimens were demonstrated; however, there was no evidence of bacteria on culture. Without disputing the concept of amicrobic pyuria, it is evident that such observations must be laid to faulty technic in culturing the organisms, but the interesting fact is that this discrepancy is nearly four times as frequent in the group receiving sulfanilamide (table 5) as in the control group.

This considerable group of purulent specimens found to be culturally negative in the experimental series makes us doubt that they are, indeed, really sterile. We must neglect for the moment the considerable number of "amicrobic pyurias" in the control group and seek some explanation of this phenomenon of increase in the number of such specimens in the sulfanilamide group.

All the patients in this group received the drug up to the time when the second specimen of urine was collected and we are faced with the possibility that excretion of sulfanilamide in the urine of these subjects effected a bacteriostatic influence when it was attempted to culture these specimens on the usual mediums.

It has already been pointed out that, in a number of instances, it had been necessary to discontinue sulfanilamide and, in table 6, an attempt has been made to correlate the bacteriologic observations with administration of the urinary antiseptic in these cases.

The differences in the amounts of the drug given were quite insignificant and cannot explain the changes noted in the status of the specimens of urine. Of the nine cases in which it was necessary to discontinue use

TABLE 5.—Pyuria

	Control Series, per Cent	Sulfanilamide Series, per Cent
Purulent urine with negative cultures.....	12	44

of sulfanilamide because of undesirable sequelae, four remained sterile throughout, three originally negative culturally became infected, and two of the specimens originally infected became negative on culture, five days after operation.

COMMENT

If there is any case for sulfanilamide, as used in the present series, it would seem to rest on a very frail foundation. We have failed to prove conclusively that there is a reduction in the number of infected specimens of urine after the drug has been taken for five days. The observation that the urine specimens of patients who were taking sulfanilamide give a higher percentage of negative cultures than do those of the control group is not necessarily conclusive. It means only that the methods used in this study for demonstration of the infecting organisms were inadequate. It would be necessary to allow several days to elapse after discontinuing the drug before the urine then obtained could be pronounced culturally negative. It is entirely possible that the presence of sulfanilamide in the specimens of urine that were cultured exerts a bacteriostatic effect and the methods of culture which were employed could not, therefore, exclude viable organisms.

The case against sulfanilamide as a routine urinary antiseptic in such postoperative cases is supported by the nine instances in which undesirable reactions have

TABLE 6.—Correlation of Bacteriologic Observations with Dosage of Drug

Bacteriologic Observations	Average Total Dosage of Sulfanilamide, Grams
Uninfected urine remaining sterile.....	156
Uninfected urine becoming infected.....	149
Infected urine becoming sterile.....	163

Purulent urine with negative cultures.....	140

occurred. The reactions observed in these nine cases were sufficiently grave to require us to discontinue administration of sulfanilamide to the subjects concerned. Because all the patients were hospitalized for the duration of the experiment, it was permissible, therefore, to persevere with the drug in the face of what would constitute a contraindication to its use under less ideal conditions. Mild reactions occurred in a number of other cases but in these nine the reaction was severe enough to require withdrawal of the drug. It should be emphasized again that sulfanilamide is a

drug not without danger, especially when administered to the elderly patient. Its use as a routine urinary antiseptic in postoperative cases is to be deprecated.

The urinary infections that exist before operation or develop afterward are, in actual experience, very rarely the cause of anxiety. Certainly a stormy convalescence owing to such infections had a much lower incidence than did undesirable reactions to sulfanilamide. Actually, in the present series, there were only three patients in each of the groups in whom febrile reactions ensued that could be regarded as characterizing a mildly stormy convalescence.

CONCLUSIONS

A study of the efficacy of sulfanilamide as a urinary antiseptic in the postoperative management of 100 cases of transurethral resection has been made.

A control series of a similar number of cases was studied concurrently.

Our experience has not demonstrated a sound basis for administration of sulfanilamide in routine postoperative management of these cases. In fact, the unfavorable reactions from it may hinder convalescence.

It is our opinion that the results of its administration in other types of surgical cases wherein the drug is expected to act as a urinary antiseptic will be similar to ours. Its routine use, therefore, seems unwarranted.

THE USE OF BENZEDRINE SULFATE IN POSTENCEPHALITIC PARKINSONISM

PERK LEE DAVIS, M.D.

AND

WINIFRED B. STEWART, M.D.

PHILADELPHIA

Benzedrine has been referred to in the literature by many chemically descriptive terms such as benzyl methyl carbinamine, alpha methyl phenylethylamine, beta phenylisopropylamine, phenylaminoethanol and beta aminopropylbenzene. We shall confine ourselves to the use of the trade name benzedrine sulfate in future reference.

Pharmacologic studies¹ have shown that benzedrine has a more profound central stimulating action on the central nervous system than either epinephrine or ephedrine. Its action has been estimated to be sustained from two to eight times as long as that of ephedrine. Its central effect is probably due to an increased cerebral blood flow and a possible chemical action on the brain itself.² Its action as a vasopressor causes the blood and spinal fluid pressures to increase.³ The use of the parasympathetic paralyzants, hyoscyamus, belladonna and stramonium enhances the sympathetic stimulating action of benzedrine, thereby increasing its pressor effects. Dameshek⁴ has shown an increased erythrocyte count during the use of this drug. Lagen,

Soley and Leake⁴ have reported an increase in the basal metabolic rate in a small series of cases.

Extremely good results have been obtained in persons in a depressed mood, in those who are easily fatigued and in the chronically exhausted and self absorbed.⁵ Following the administration of benzedrine, an improvement of more than 8 per cent had been noted in intelligence scores.⁶ Benzedrine sulfate has proved ineffectual in catatonic stupors.⁷ Favorable results have been obtained in anchoring the symptoms of those suffering from orthostatic hypotension.⁸ In some cases of myasthenia gravis, good results have been obtained by the use of benzedrine as a supplement to prostigmine therapy.⁹ Benzedrine has been reported to be three times as effective as ephedrine in narcolepsy and has afforded almost complete relief from cataplectic symptoms.¹⁰ In some of these cases in which ephedrine proved inactive even in large doses, benzedrine was effective in small doses.

Recently reports of small series of cases¹¹ have tended to show the effectiveness of benzedrine sulfate in postencephalitic parkinsonism. They have shown that the useful action of this drug is chiefly on the subjective symptoms, although 100 per cent of the patients suffering with oculogyric crises were relieved. Likewise in 100 per cent of the cases an increase in energy and disappearance of drowsiness was noted. The strength and muscular rigidity were also favorably affected, though to a less degree. In a disease respecting neither age nor sex, which marches so gradually and relentlessly to progressive helplessness, a drug which may stay its progress or offer some relief is worthy of trial. It was with this purpose in mind that we began this study in July 1936.

From the neurologic wards and the outpatient department of the Philadelphia General Hospital, ninety cases of parkinsonism were chosen for our study. In only seventy-four of these cases were we able to complete our observations, owing to discharges and transfers of seven ward patients and to the lack of cooperation of nine of our clinic patients. We feel satisfied that in

seventy-one of these cases the etiology of the parkinsonian syndrome is chronic epidemic encephalitis. In three, the possibility that the parkinsonism is of the idiopathic type must be considered but, as it is well recognized that the differential diagnosis is frequently impossible to establish and since here the evidence was in favor of the postencephalitic type of the disease, we feel that these cases could be included.

The range of age was from 15 to 68 years. There are three patients under 20 years of age, seventeen in their twenties, twenty-four in their thirties, nineteen in their forties, eight in their fifties and three in their sixties. There were forty-three men and thirty-one women.
